APPENDIX F

Caribou Migration Timing Analysis

TECHNICAL MEMORANDUM

DATE August 30, 2021

Project No. 19134270-515-TM-Rev2

TO Alexandre Lavallee
Agnico Eagle Mines Limited

CARIBOU MIGRATION TIMING WITH THE WHALE TAIL HAUL ROAD AND ALL-WEATHER ACCESS ROAD

1.0 INTRODUCTION

Studies completed to support the environmental assessment of the Whale Tail Project demonstrated that the Lorillard caribou herd has the greatest potential to interact with the Meadowbank Mine (Mine), the Whale Tail Haul Road (WTHR) and the All-weather Access Road (AWAR) during spring and fall seasons (Golder 2017; Figure 1). The Government of Nunavut has defined seasonal migrations as occurring from April 5 to May 28 for spring and September 22 to December 15 for fall (Caslys 2015). The Mine implements a Terrestrial Ecosystem Management Plan (TEMP) to protect caribou from Mine-related effects including safe passage across the WTHR and AWAR. The road-related mitigation of the TEMP includes use of partial and full road closures and convoys. The WTHR and AWAR closure mitigation is currently triggered by exceedance of a caribou group size threshold (GST), which requires caribou group size observations to assess against the threshold.

The initial spring GST value of 12 in the TEMP (Agnico Eagle 2019) was static and was based on historical monitoring data collected only along the AWAR. The spring GST value(s) was updated to 60 for the Haul Road and 45 for the AWAR based on analyses completed by the Government of Nunavut and reviewed with the Mine's Terrestrial Advisory Group (TAG) on March 16, 2021. The GST for fall is 112 for both the Haul Road and AWAR. Temporal analysis of longer-term monitoring data show that caribou groups sizes vary within and among years as might be expected (EDI 2019; Golder 2020). As discussed with the TAG previously, the approved Project Description, including stockpile size, was designed around a total of 18 days of road closure for caribou annually. The low and static GST value coupled with variability in caribou group sizes triggered 60 days of road closures in 2019. Variable caribou group sizes also make predictions of road closures uncertain and reactive. As a result, the GST approach generally makes planning resupply to the stock-pile and mill during WTHR and AWAR closures a difficult Mine operational constraint to manage. Without resupply, the stockpile at the Mine site supplies the mill for about 15 days.

The TAG and Mine are currently evaluating alternate ways to maximize protection for caribou while making road closures more manageable for Mine operation. For example, the Mine has proposed the use of a cap and pulse system where the cap is a maximum number of days roads will be closed and the pulse represents alternative mitigations such as convoys. The Kivalliq Inuit Association (KivIA) has also recommended alternative timing of closures that allow the lead caribou to move through more easily as suggested by Inuit Qaujimajatuqangit (IQ) holders. One approach that may address the uncertainty of when road closures would occur includes if the fall and spring migrations through the Mine are annually predictable. If so, then road closures could be scheduled to occur at certain times of the year when they maximize the intended benefit to caribou.

Telemetry collars are typically deployed in a manner (e.g., semi-random deployment) such that collared animals represent a herd, which is important for herd management and conservation. Collars provide the location of animals based on fix frequencies to satellites that may occur up to multiple times in a day. Fix frequencies for collared Lorillard caribou range from once per week (pre-2006) to every three hours (since 2009). It is possible to measure the distribution of dates of collared caribou migrated through the Mine and roads area on an annual basis. Comparison of distributions among years make it possible to determine whether the timing of caribou migration through the Mine and roads area is annually predictable. The distribution of collar data can also be compared to the distribution of ground counts of caribou groups monitored for road closure. The first objective of this analysis was to determine whether timing of migration through the Mine area is predictable during spring and fall based on collar data. The second objective was to explore relationships between collared caribou distribution and patterns in observed abundances of caribou-based group sizes from ground counts. If migration through the Mine area is predictable, then road closures can be scheduled to occur when most beneficial to caribou rather than the current reactionary practice of GST. The analysis undertaken is of exploratory nature.

Preliminary results were presented to the Mine's Terrestrial Advisory Group (TAG) on March 16, 2021. Following this meeting, the KivIA provided comments about the results represented (Gunn and Poole 2021). In summary, the comments requested:

- 1) Clarity on probability density distribution meaning and comparability with ground counts.
- 2) Results on the mean and range of migration length.
- 3) Removal of years with three or fewer collared caribou.

Additional analysis and information has been incorporated to address the comments by the KivIA.

2.0 METHODS

Two north-south reference lines were placed along and beyond the WTHR and AWAR to maximize the number of collared movements (i.e., animals that do and do not interact with the WTHR and AWAR). The WTHR and AWAR do not have a straight north-south alignment and therefore cannot be used standardize the timing of migration. In contrast, a straight north-south reference line does standardize timing because it occurs at the same point in space regardless of where a caribou encounters it. One north-south reference line was placed at the most western point of the WTHR and AWAR to capture migration of caribou from western wintering grounds to eastern calving grounds (i.e., the spring reference line; Figure 1). A second north-south reference line was placed at the most eastern point of the WTHR and AWAR to capture migration of caribou from eastern calving grounds to western wintering grounds (i.e., the fall reference line; Figure 1).

Caribou movement trajectories were estimated between subsequent telemetry locations, then trajectories were separated based on a unique caribou identifier (caribou ID), year, and season. Pre-defined seasonal migration periods (Caslys 2015) were buffered by an additional 7 to 10 days to maximize migration trajectories and the number of reference line interaction dates; buffered dates were used to define movement trajectories occurring during spring and fall migration. Buffered movement trajectories occurring March 31 to June 6 (inclusive) were considered spring migration, and buffered movement trajectories occurring September 1 to December 31 (inclusive) were considered fall migration. For each spring trajectory, dates of intersection with the spring reference line were predicted; fall dates of intersection were predicted for fall trajectories using the fall reference line. Dates of intersection were predicted based on the date and time of telemetry locations either side of the reference line. When a trajectory intersected with a reference line more than once during a season, the earliest date was used as the estimated date of intersection. Intersection dates (i.e., the standardized timing of migration) were converted to Julian days (i.e., day number of year), then stratified by caribou ID, year, and season. For clarity, the intersection dates are not intended to represent the beginning, middle, or end of caribou migration but rather provide a standardized date that describes when caribou are moving through a specific place during migration.

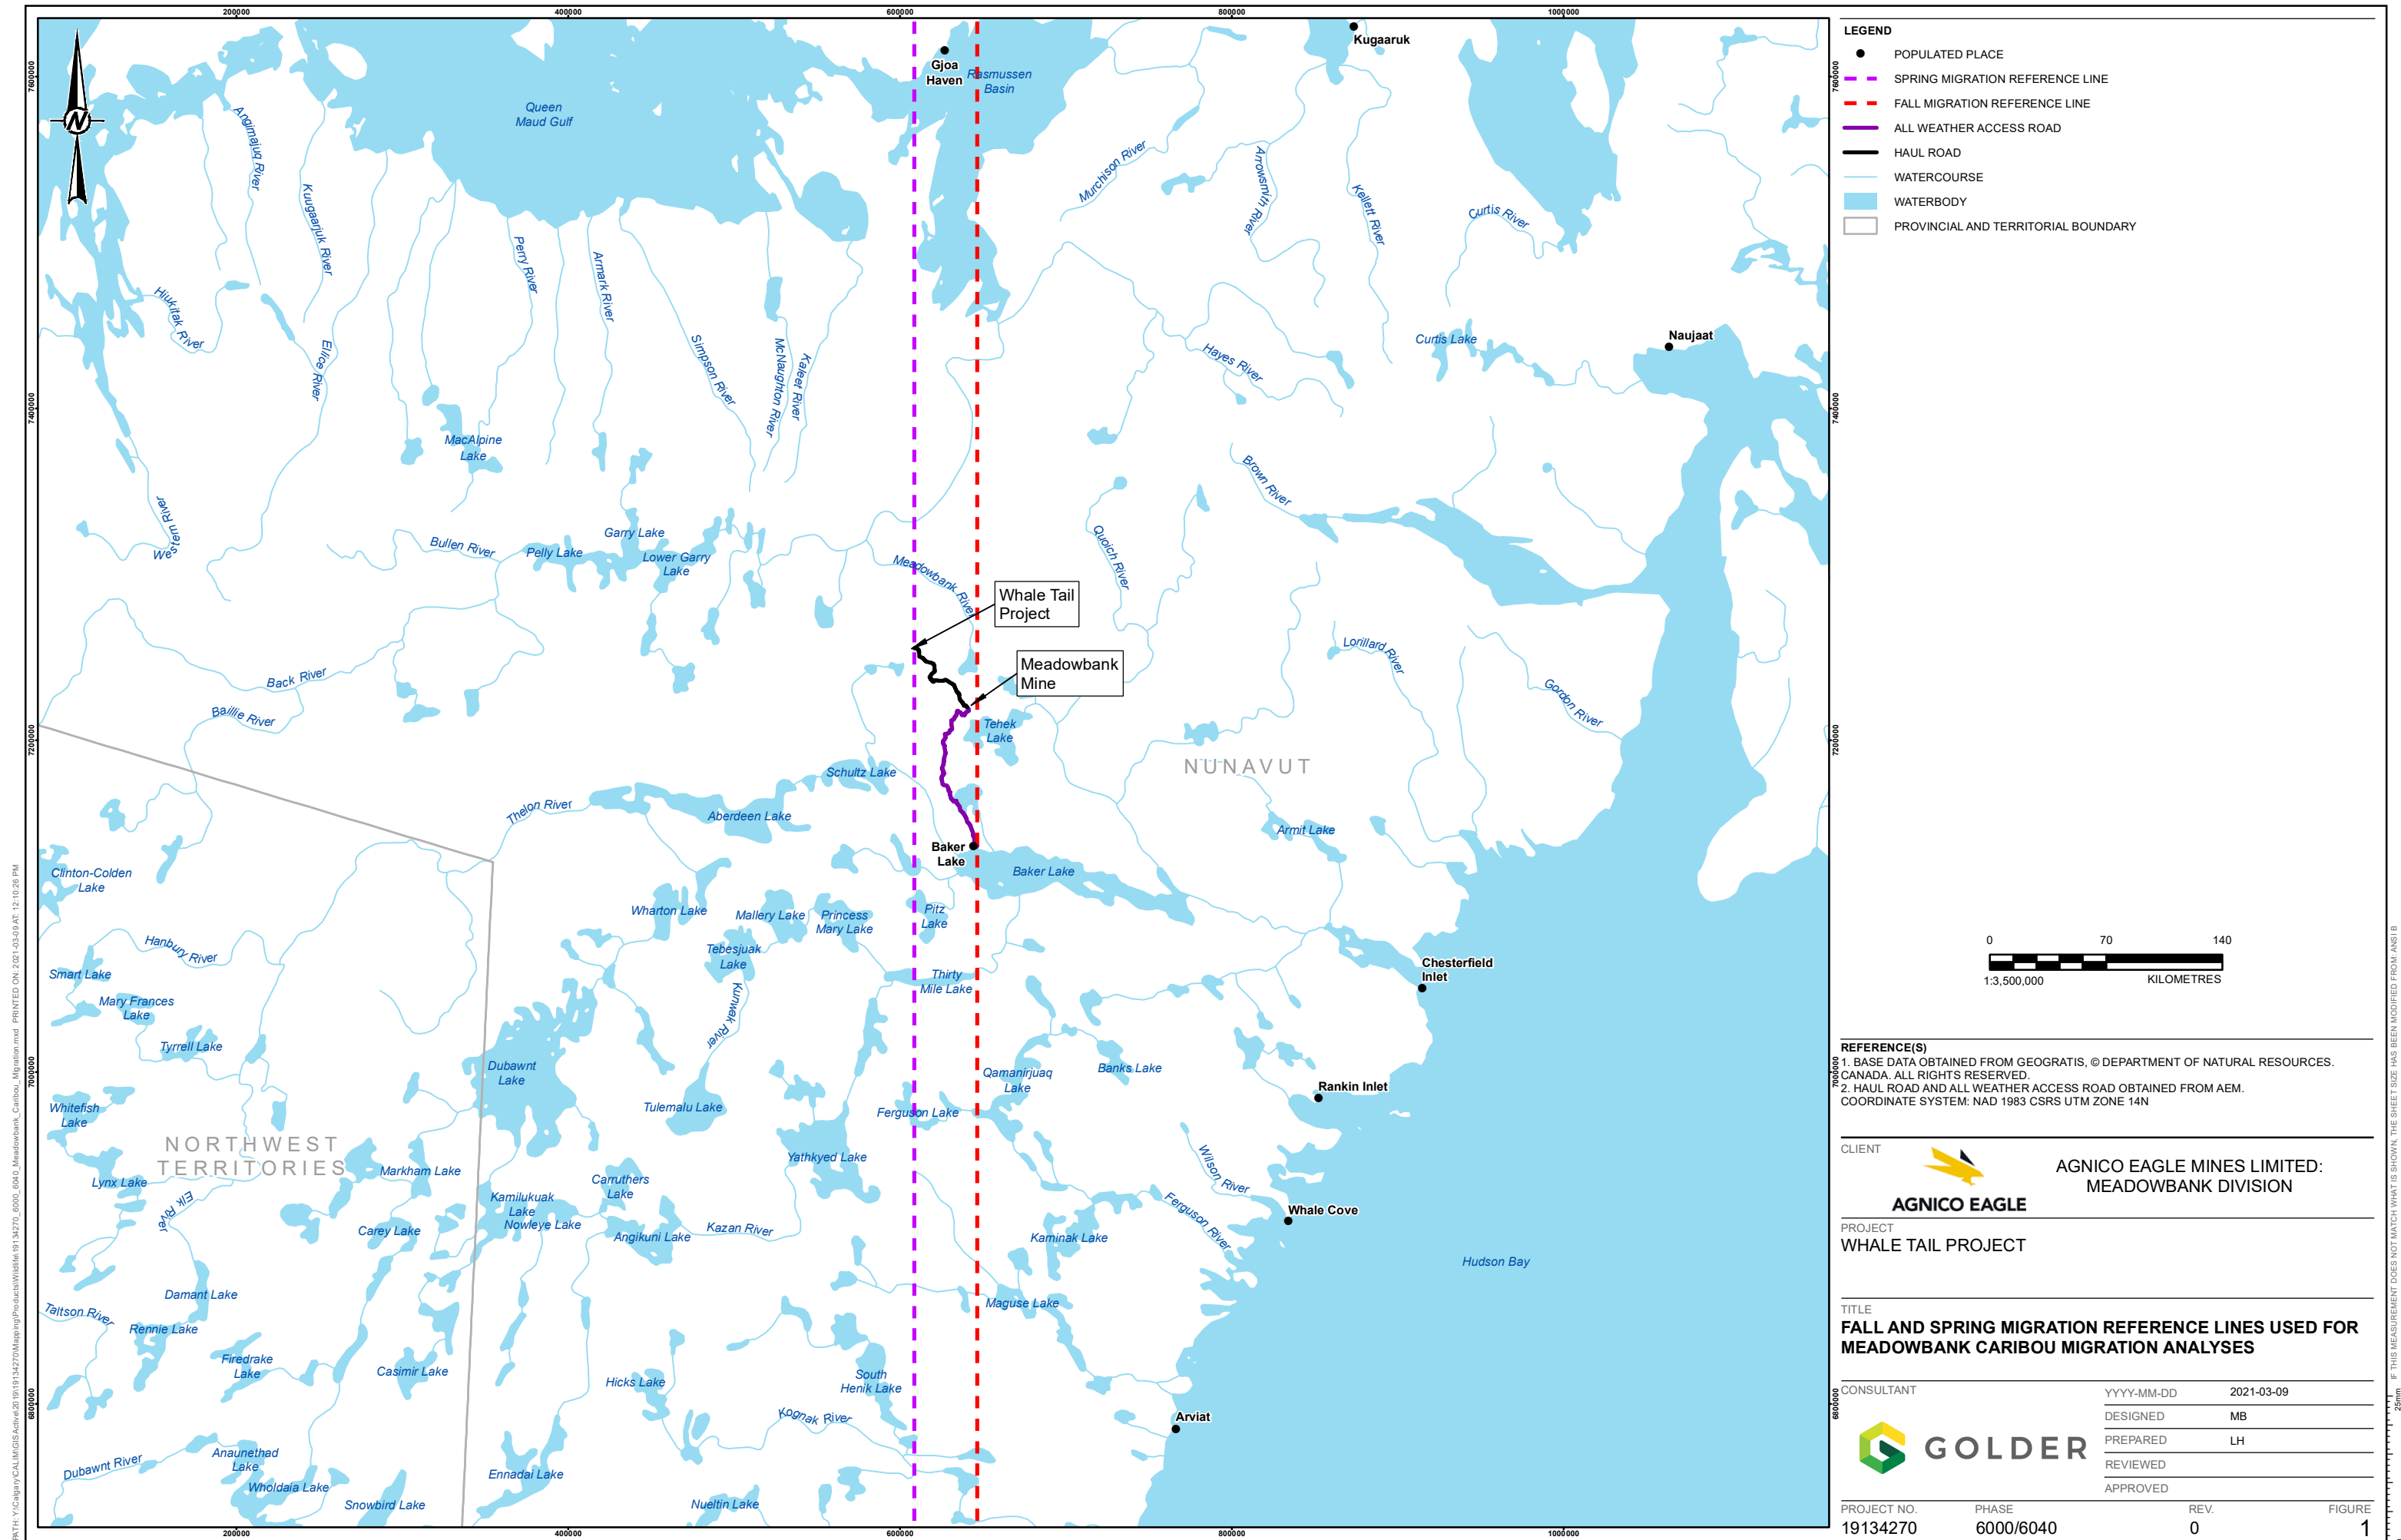

To meet the first objective of this analysis, inter-annual variation in migration trends was assessed visually. To facilitate visual comparison of migration trends, probability density plots were created. Probability density plots can be interpreted similarly to histograms in that both plots display the general shape and spread of continuous data, except probability density plots represent the probability of obtaining the range of values represented on the x-axis and histograms represent the frequency of x-axis values obtained (Figure 2). In this case, the x-axis reflects the date values of intersection with reference lines for the spring and fall migrations of Lorillard collared caribou.

The KivIA have highlighted the importance of protecting migratory leaders (i.e., the first wave of individuals interacting with reference lines) for preserving natural migratory patterns among the Lorillard caribou herd. Because fall migration appeared to be multimodal (i.e., caribou interacted with the fall reference line in multiple waves), the fall season was split into an early and late period, and inter-annual variation in fall migration was considered for each period separately. Migrations by leading caribou were, therefore, considered in early fall. Start and end dates for early and late fall periods were determined by visually assessing telemetry and ground observation data collected 2009–2020. Early migration peaks consistently occurred before Julian day 290 (i.e., October 17) whereas later migration peaks consistently occurred after Julian day 290. Therefore, interactions with the fall reference line occurring September 1 to October 17 were considered early fall and interactions occurring October 18 to December 1 were considered late fall.

Inter-annual variation in migration trends was also estimated using linear mixed-effects models, where caribou ID was included as a random intercept to account for correlated migration behaviour of the same animal, and year was included as a fixed effect. A one-way analysis of variance (ANOVA) assuming Type II error was used to test inter-annual variation in migration trends (i.e., the fixed effect of year). Post-hoc comparisons (i.e., Tukey Contrasts) were completed between pairs of years to determine statistically significant differences in migration trends over time. Adjusted *p*-values are reported to account for multiple testing. All statistical analyses were implemented in R (R Core Team 2021) using the *lmerTest* (Kuznetsova et al. 2017), *car* (Fox and Weisberg 2019), and *multcomp* (Hothorn et al. 2008) packages.

To address the second objective of this analysis, ground observations of caribou groups from 2018 and 2019 were compared with seasonal migration trends obtained from telemetry data for years 2018 and 2019 to determine whether similar migration timings were obtained. Given the proximity of the reference lines to Mine roads, the telemetry and ground observations are comparable because they are measuring approximately the timing of caribou movements through the roads area. Years 2018 and 2019 were selected for these comparisons because substantial effort was allocated to ground-based caribou surveys in these years, and because the WTHR construction ceased in 2018. Lastly, the dates when 50% of caribou had completed migration were estimated for ground observations and telemetry data for both 2018 and 2019, then compared.

KivIA proposed that annual variations in traffic and road closures may have contributed to annual variations in timing of migration (Gunn and Poole 2021). In response, an additional analysis was completed to assess the effect of WTHR construction on spring and fall migration patterns. Migration data collected before 2018 were pooled into 'pre-WTHR' and data collected in 2018 and 2019 were pooled into 'post-WTHR', by season and period. An ANOVA assuming Type II error was used to test variation in migration trends pre- and post-WTHR by season, with year and caribou ID included as random intercepts.

Figure 2: Probability density plot (translucent smoothed curve) and histogram plot (teal bars) depicting the shape and spread of continuous spring migration data. The probability density plot represents the continuous probability of obtaining the range of spring migration dates whereas the histogram plot represents the frequency of spring migration dates obtained. This figure was simulated as an example and does not depict any particular year of spring migration data.

3.0 RESULTS

Table 1 and Figure 3 summarize mean spring migration dates, with associated sample sizes and standard deviations, obtained from telemetry data collected 2005–2019. Standard deviations represent the spread and variation of data, assuming a normal distribution; one standard deviation represents 67% of the data and two standard deviations represent 96% of the data. Standard deviations were not provided for years in which $n = 1$ (i.e., a sample size of one caribou interaction was available).

The estimated date of spring migration pooled across all years was Julian day 121, or May 1 (April 30 on leap years¹; Table 1; Figure 3). One standard deviation, or 67% of spring migrations, occurred between April 21 and May 10 and two standard deviations, or 96% of all spring migrations, occurred between April 11 and May 20 (Table 1; Figure 3). The earliest mean spring migration date occurred in 2005 and 2015 (i.e., April 21) and the latest mean spring migration date occurred in 2013 (i.e., May 17; Table 1; Figure 3). Standard deviations ranged from narrow (i.e., 5 days in 2013) to wide (i.e., 33 days in 2005), and were 15 days or shorter for most years (Table 1; Figure 3).

Spring migration distributions differed significantly across all years ($\chi^2 = 44.49$, $df = 8$, $p < 0.0001$). However, when Tukey contrasts were completed among pairs of years (Table 1 of Attachment 1), 83% of years were statistically similar ($p > 0.05$) and only 17% of years differed significantly ($p < 0.05$). Among statistically significant paired year contrasts, the largest difference between years was 26.2 days; the mean absolute difference (pooled across all pair comparisons, 2005–2019) was 9.8 days.

Based on comments from the KivIA following the TAG meeting #8 on 16 March 2021 (Gunn and Poole 2021), spring migration years with $n \leq 3$ caribou interacting with reference lines were removed to provide more robust data for visualization and analyses. Therefore, years 2005, 2014, 2015, and 2016 were removed due to low sample sizes (i.e., $n = 3, 1, 3$, and 3, respectively). The estimated mean date of spring migration across years was two days later than previously estimated (Table 1; Figure 3) and was Julian day 123 (May 3; Figure 4). Removing years with $n \leq 3$ resulted in a smaller standard deviation (i.e., 9.2 days vs. 9.7 days; Table 1; Figure 3). A total of 67% of spring migrations (i.e., one standard deviation) occurred between April 24 and May 12, and 96% of spring migration (i.e., two standard deviations) occurred between April 14 and May 21 (Figure 4). Spring migration distributions differed significantly across years ($\chi^2 = 39.58$, $df = 4$, $p < 0.0001$). Tukey contrasts (Table 2 of Attachment 1) indicated that 50% of years were statistically similar ($p > 0.05$) and 50% of years were statistically different ($p < 0.05$). The largest difference between years was 23.7 days, and the mean absolute difference (pooled across all pair comparisons, 2011–2019) was 10.6 days. Overall, the reduction in years analysed based on sample size requirements did not result in large changes to migration timing, duration, and pooled absolute differences but did reduce the number of year-to-year comparisons of distributions that were statistically similar.

In 2018, the date at which approximately 50% of caribou were estimated to have migrated across the spring reference line, based on ground observations, was Julian day 108 (or April 18; Figure 5), which was 13 days earlier than the date estimated by telemetry data (i.e., Julian day 120 or May 1; Table 1). The estimated date of spring migration was later in 2019 (i.e., Julian day 114 or April 24 vs. Julian day 108 or April 18; Figure 5) based on ground observations. Telemetry data for 2019 indicated that the estimated date of spring migration was also April 24 (Table 1).

¹ All dates summarized henceforth assume non-leap years.

Figure 6 depicts the multimodal distribution of mean fall migration dates prior to separating data into early and late fall periods. Fall migration years with $n \leq 3$ caribou interacting with reference lines were also removed to provide more robust data for visualization. The years 1998, 1999, 2000, 2001, and 2014 were removed due to low sample sizes (i.e., $n = 1, 1, 1, 2$, and 2 , respectively; Figure 7). Based on 14 caribou, the mean early fall migration date for 2018 was Julian day 256, or September 13 (Table 2). One standard deviation, or 67% of early fall migrations, occurred between September 6 and September 20 in 2018, and two standard deviations, or 96% of early fall migrations, occurred between August 30 and September 27 in 2018 (Table 2). Because only one year of data (i.e., 2018) was available to estimate early fall migration, statistical analyses could not be completed.

The mean late fall migration date was Julian day 312, or November 8 (Table 2). One standard deviation, or 67% of late fall migrations, occurred between October 25 and November 23, and two standard deviations, or 96% of late fall migrations, occurred between October 11 and December 7 (Table 2). Late fall migration distributions differed significantly across years ($\chi^2 = 262.76$, $df = 6$, $p < 0.0001$). Tukey contrasts (Table 3 of Attachment 1) indicated that 33% of years were statistically similar ($p > 0.05$) and 67% of years were statistically different ($p < 0.05$). The largest difference between years was 36 days, and the mean absolute difference (pooled across all pair comparisons, 2004–2017) was 17 days.

In 2018, the estimated date at which approximately 50% of total caribou were recorded from ground observations was Julian day 286 (or October 13), which was 22 days later than the date estimated by 50% of telemetry data (i.e., Julian day 264 or September 21; Figure 8) and inclusive of both early and late fall periods. Because telemetry data were not available for fall 2019, comparisons between ground and telemetry observations could not be made for 2019.

Spring migration distributions did not vary pre- and post-WTHR construction ($\chi^2 = 1.3604$, $df = 1$, $p = 0.24$), nor did late fall migration distributions ($\chi^2 = 0.0455$, $df = 1$, $p = 0.83$). Early fall pre- and post-WTHR construction distributions were not compared because the within year trend for 1999, 2000 and 2001 are characterized by a single collared animal (Table 2) and would limit the temporal comparison to a single pre-construction (2016) and post-construction 2018 year (Figure 7).

Table 1: Mean spring migration dates, and associated sample sizes (*n*), date ranges for standard deviations, and widths of standard deviations, for Lorillard caribou using telemetry data collected 2005–2019. Distributions associated with these data are visually presented in Figure 3.

Year	Sample Size (<i>n</i>)	Mean Date of Spring Migration	+/- One Standard Deviation (Dates)	One Standard Deviation Width (# of Days)	+/- Two Standard Deviations (Dates)	Two Standard Deviation Width (# of Days)
2005	3	Apr 21	Apr 4 – May 7	33	Mar 19 – May 24	66
2011	6	May 6	May 3 – May 9	6	Apr 30 – May 12	12
2012	4	May 3	Apr 26 – May 11	15	Apr 19 – May 18	29

Figure 3: Distribution of estimated Julian day of spring migration based on telemetry data collected from the Lorillard caribou herd 2005–2019. The solid dark grey line indicates the mean spring migration date across all years, or when 50% of the caribou are predicted to have completed spring migration (day 121, or May 01). The dashed grey lines indicate one standard deviation from the mean (April 21–May 11) and the dotted grey lines indicate two standard deviations from the mean (April 11–May 21). A distribution was not possible for 2014 due to the small sample size of migration data ($n = 1$ caribou). Mean spring migration dates, sample sizes, and standard deviations for these data are summarized by year in Table 1.

Figure 4: Distribution of estimated Julian day of spring migration based on telemetry data collected from the Lorillard caribou herd 2011–2019. Data were constrained to years with n caribou ≥ 4 . The solid dark grey line indicates the mean spring migration date across all years, or when 50% of the caribou are predicted to have completed spring migration (day 123, or May 3). The dashed grey lines indicate one standard deviation from the mean (April 24–May 12) and the dotted grey lines indicate two standard deviations from the mean (April 14–May 21).

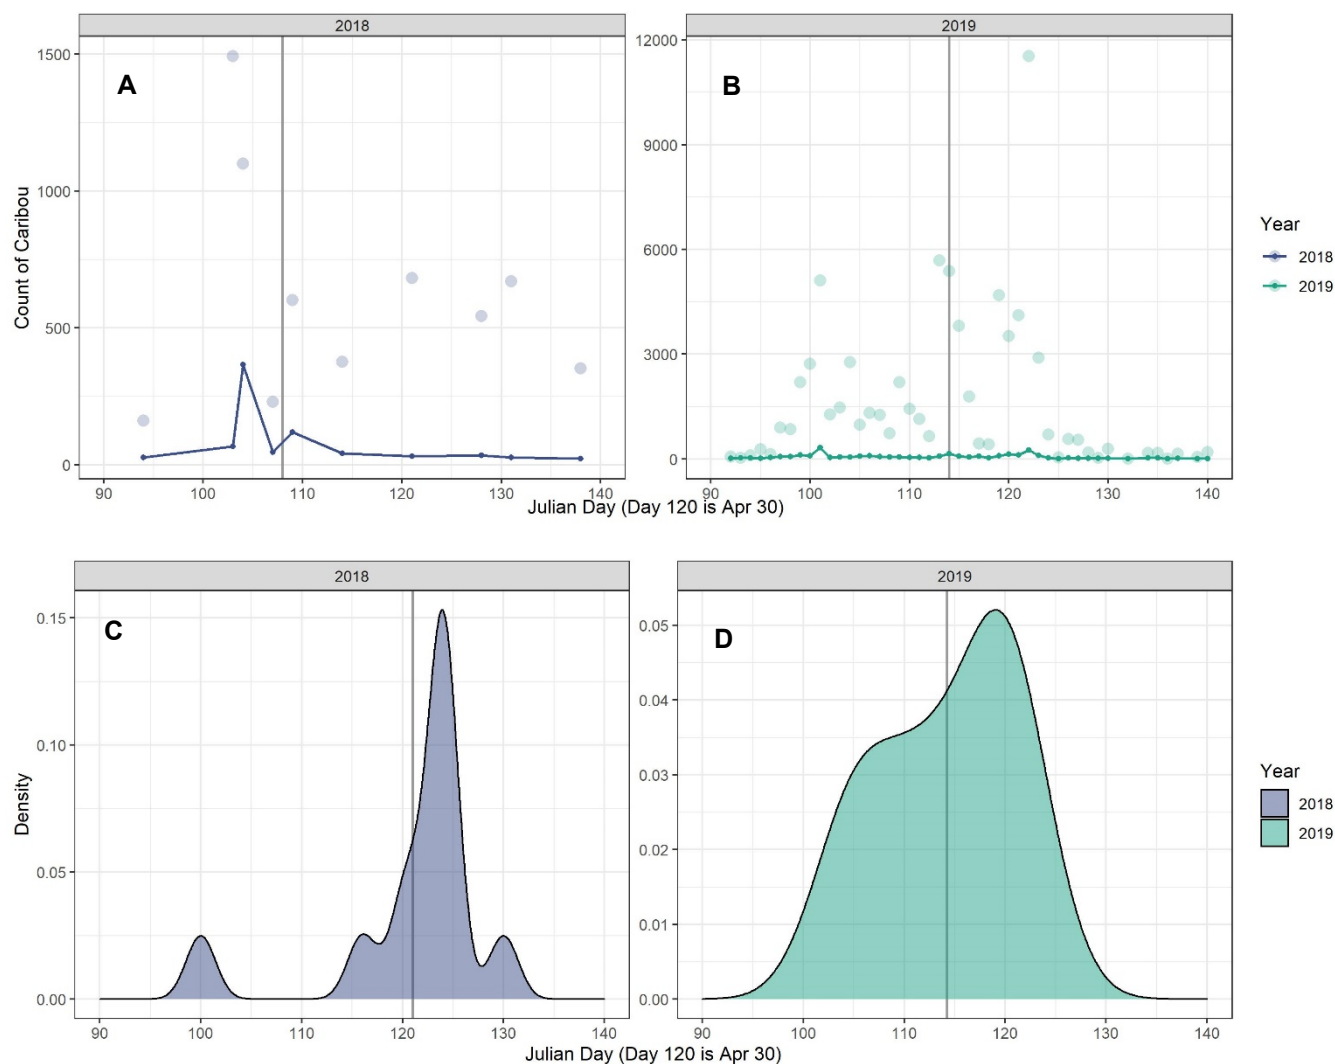

Figure 5: Comparison of spring migration dates based on ground observations (panels A and B) and telemetry data (panels C and D) from the Lorillard caribou herd in 2018 and 2019. A total of 6,645 caribou among 147 groups and 75,973 caribou among 996 groups were observed in 2018 and 2019, respectively (panels A and B). Sample sizes for telemetry data were $n = 11$ caribou in 2018 and $n = 8$ caribou in 2019 (panels C and D). Transparent circles indicate total observed caribou per Julian day and solid points connected by solid lines indicate mean caribou group size observed per Julian day (panels A and B). Probability density plots depict the estimated distribution of spring migration per year from telemetry data (panels C and D). Solid grey lines on all panels (A–D) indicate the date at which 50% of caribou were estimated to have completed spring migration.

Figure 6: Distribution of estimated Julian day of fall migration based on telemetry data collected from the Lorillard caribou herd 2001–2018. Distributions were not possible for 1998, 1999, and 2000 due to small annual sample sizes of migration data ($n = 1$ caribou).

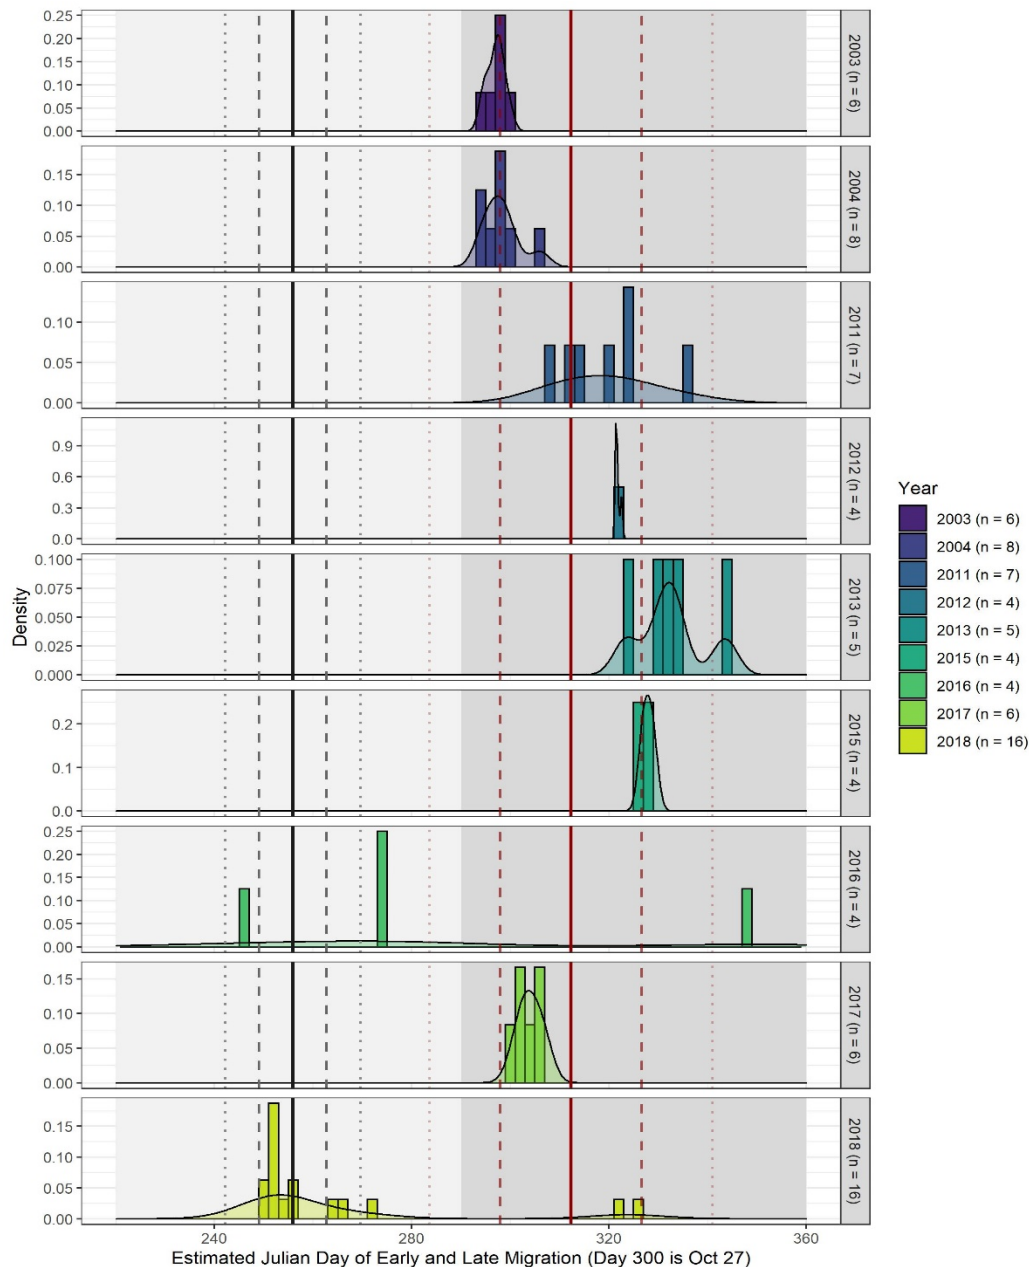

Figure 7: Distribution of estimated Julian day of early and late fall migration based on telemetry data collected from the Lorillard caribou herd 2003–2018. Light grey boxes from day 220–290 represent the early fall period and dark grey boxes from day 291–360 represent the late fall period. Data were constrained to years with n caribou ≥ 4 . The solid dark grey and dark red lines indicate the mean early and late fall migration date across all years, respectively (early: day 256, or Sep 13; late: day 312, or Nov 8). The dashed grey lines indicate one standard deviation from the mean early fall migration date (Sep 6–20) and the dotted grey lines indicate two standard deviations from the mean early fall migration date (Aug 30–Sep 27). The dashed red lines indicate one standard deviation from the mean late fall migration date (Oct 25–Nov 23) and the dotted red lines indicate two standard deviations from the mean late fall migration date (Oct 11–Dec 7). Mean early and late fall migration dates, sample sizes, and standard deviations for these data are summarized by year in Table 2.

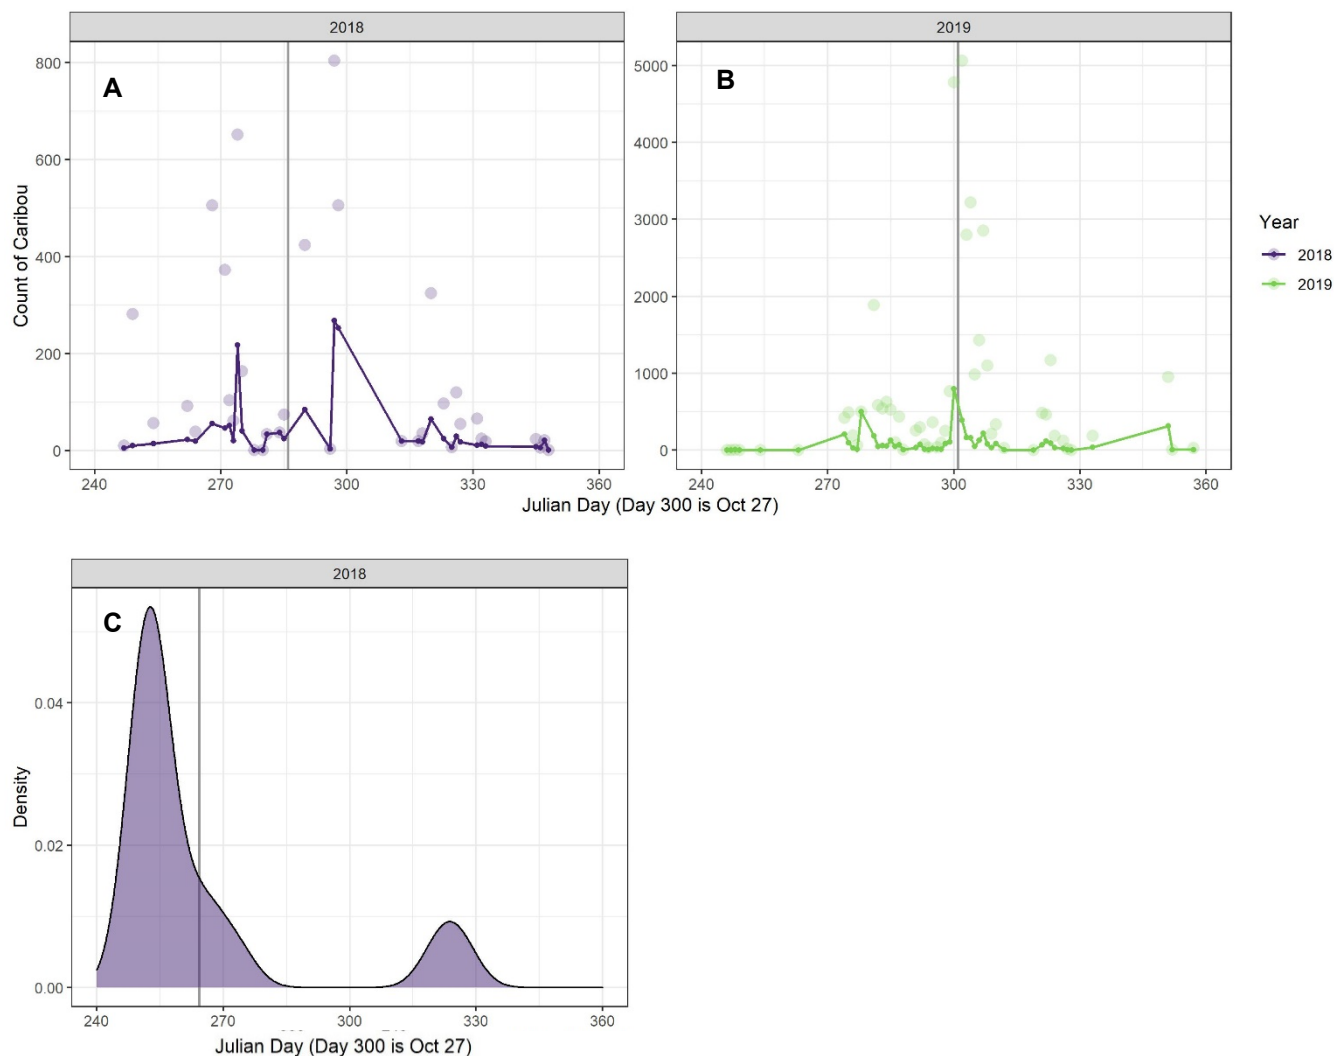

Figure 8: Comparison of fall migration dates based on ground observations (panels A and B) and telemetry data (panel C) from the Lorillard caribou herd in 2018. A total of 5,068 caribou among 123 groups and 35,008 caribou among 323 groups were observed in 2018 and 2019, respectively (panels A and B). Sample sizes for telemetry data were $n = 16$ caribou in 2018 (panel C); telemetry data were not available for fall 2019. Translucent circles indicate total observed caribou per Julian day and solid points connected by solid lines indicate mean caribou group size observed per Julian day (panels A and B). Probability density plots depict the estimated distribution of fall migration per year from telemetry data (panel C). Solid grey lines on all panels (A–C) indicate the date at which 50% of caribou were estimated to have completed fall migration.

4.0 RECOMMENDATIONS

The reduction in years analysed based on sample size requirements did not result in large changes to migration timing, duration and pooled absolute differences but did reduce the number of year-to-year comparisons of distributions that were statistically similar. Although there was some variation in migration timing between years in the larger dataset, results for spring migration indicated that annual timing of caribou migration through the Mine and roads area was relatively consistent (i.e., predictable) across years. The mean spring migration date was May 01 over all years. Across years, 96% individuals on average migrated through the Mine area over a period of 25 days (mean of annual 2 standard deviations). Comparison of telemetry and ground observations indicated similarities between the two datasets, particularly for 2019 where more ground observations were available (996 groups counted in 2019 vs. 147 in 2018). The cap combined with alternative mitigation such as convoys (pulse) and periodic road closures could be applied to maximize the number of caribou exposed to roads without Mine-related traffic. For example, use of all Road closures days (cap) for 18 consecutive days applied between April 21 to May 11 (i.e., almost one standard deviation of the mean over all years) would cover the mean migration timing for all but one year. In a typical year, 96% of caribou may benefit from any mitigation (cap and/or pulse) if applied for a 25-day period.

Fall migration was more variable than spring migration and, in 78% of years (7 of 9 years; Figure 7), caribou moved through the Meadowbank Mine area during the late fall period beginning October 18. The mean date of late fall migration was November 8 over all years. Across years, 96% individuals on average migrated through the Mine area over a period of 7 days (mean of annual two standard deviations) during late fall. In 2016 and 2018, collared caribou also moved through the Meadowbank Mine area during the early fall period (Figure 7). While migration timing was generally more variable during fall, the duration of migration in either early or late fall was shorter than the duration of spring migration. Under a cap and pulse mitigation strategy, fewer consecutive days of road closures may be required during fall migration and may be more generally beneficial to caribou during later fall given the lower frequency of migration during early fall. In lieu of road closures during early fall, pulse mitigation (e.g., convoys) could be scheduled for approximately two weeks in September to maximize the number caribou exposed to roads without Mine-related traffic and while continuing to resupply the stockpile with ore for the mill.

Further exploratory analysis aimed at explaining annual differences in the timing of spring and fall migration may be completed with environmental covariates such as snow conditions (Mallory et al. 2020) or weather (Gurarie et al. 2019). If differences can be explained by readily available information such as weather, then it may be possible to forecast when mitigation should be applied annually. When 2019 and more current telemetry data are available, further analyses can be carried forward with additional comparisons to ground observations during both seasons. Lastly, the results of these analyses should be reviewed with the TAG to establish desired caribou protection outcomes (e.g., protection of lead caribou, protection of maximum number of caribou, or both) and to determine when, and for how long, cap and pulse mitigation should be applied to reach the desired outcomes.

5.0 CLOSURE

Table 2: Multiple post-hoc comparisons of mean spring migration dates for collared Lorillard caribou, 2011–2019. Years with $n \leq 3$ caribou were excluded from comparisons (i.e., 2005, 2014, 2015, and 2016). Bold and shaded rows indicate significant differences between pairs of years (i.e., $p < 0.05$).

Comparison Years	Estimate	Standard Error	Z Test Statistic	Tukey Adjusted p -value ¹
2012 - 2011	-1.86	4.07	-0.46	0.99
2013 - 2011	10.65	4.07	2.62	0.07
2018 - 2011	-5.64	3.20	-1.76	0.39
2019 - 2011	-13.04	3.51	-3.72	0.00

-------------------	------------------------------

SECTION 1 • EXECUTIVE SUMMARY

A Baker Lake Hunter Harvest Study (HHS) conducted from 2007 to 2015 was relaunched in 2019 and continued into 2021. The study included more than 50 participants of which 39 reported harvesting Caribou (*Rangifer tarandus*). Given an estimated 300 to 350 active hunters in the Hamlet of Baker Lake, the HHS represents from 11 to 13% of hunters in the community. With a total reported Caribou harvest of 513 in 2021, the total Caribou harvest in Baker Lake is estimated to range from 3,946 to 4,664 Caribou. This estimate is likely high because the current study attracted some of the more successful hunters (e.g., Baker Lake Hunters and Trappers Organization members) in the community.

Compared to the average across other years, Caribou were harvested at a higher percentage within 5 km of the All-Weather Access Road and at a lower percentage within the Regional Study Area in 2021. Harvest levels in 2021 in close proximity to mining facilities were well within threshold levels established during the impact assessment.

Two Muskox (*Ovibos moschatus*), 20 Wolverine (*Gulo gulo*), and 26 Wolves (*Canis lupus*) were harvested in 2021, which is lower than in 2020. Arctic Fox (*Vulpes lagopus*) and Red Fox (*Vulpes vulpes*) were also harvested.

Lake Trout (*Salvelinus namaycush*) and Lake Whitefish (*Coregonus clupeaformis*) were the most common species caught by fisherman and were reported at considerably higher numbers than in 2020.

SECTION 2 • OVERVIEW

As outlined in the original TEMP (Cumberland 2006) and the June 2019 version (Agnico Eagle 2019), and as a requirement of NIRB Project Certificate No. 004 Terms and Conditions 51 and 54, the Baker Lake Hunter Harvest Study (HHS) was initiated in March 2007 by Agnico Eagle. The HHS was conducted in association with the Baker Lake Hunters and Trappers Association (HTO) to monitor and document the spatial distribution, seasonal patterns, and harvest rates of hunter kills and angler catches within the Meadowbank Regional Study Area (RSA).

After low participation during the first year of the study, methods were strategically adapted, participation increased steadily, and valuable information on harvest patterns in the Baker Lake area was collected. The HHS, through regular visits, contributed to developing a strong relationship with local harvesters, the HTO, and the Government of Nunavut, Department of Environment (GN). Data were provided annually in monitoring reports from 2007 to 2015 and in 2019 to 2020.

The HHS was suspended for three years (2016 and 2018) to develop new approaches and direction. Following consultation with the HTO, Kivalliq Inuit Association (KivIA), GN, and other agencies in November 2016 (Winnipeg) and June 2017 (Ottawa), Agnico Eagle reinitiated the HHS in March 2019, which for the first time also encompassed the Whale Tail RSA as part of the Meadowbank Complex. The study approach was similar to previous years, but suggestions and guidance received during the consultation period were incorporated into the study. The study was conducted through 2020 and 2021 and continues into 2022.

SECTION 3 • OBJECTIVES

The primary objectives of the HHS are to monitor potential project-related effects on harvesting of wildlife by residents of Baker Lake. This objective is achieved by estimating the following key metrics:

1. The distribution of Caribou (*Rangifer tarandus*), Muskox (*Ovibos moschatus*), and Wolverine (*Gulo gulo*) harvest by residents of Baker Lake; and
2. The total level (or an index of) Caribou, Muskox, and Wolverine harvest by residents of Baker Lake.

Other objectives of the HHS, established in consultation with the Terrestrial Advisory Group (TAG), or other participants include:

- 1) Supporting creel surveys by gathering information on Arctic Char (*Salvelinus alpinus*), Lake Trout (*Salvelinus namaycush*), Lake Whitefish (*Coregonus clupeaformis*), and Arctic Grayling (*Thymallus arcticus*) catch rates and Inuit-use patterns in the Baker Lake area;
- 2) Understanding regional distribution of hunting and fishing activity;
- 3) Investigating seasonal timing of hunting and fishing activity; and
- 4) Determining whether increased harvest and catch rates are associated with the Meadowbank All-Weather Access Road (AWAR) and Whale Tail Hail Road (WTHR).

As discussed during consultation with stakeholders, the HHS will further seek to: a) increase and maintain the hunter participant rate in the future of the program; b) improve resource protection; c) improve hunter awareness and education; d) increase the integration of Inuit Qaujimajatuqangit and Traditional Knowledge; e) increase availability of data to support a collective approach to understanding wildlife harvest; and f) assist Agnico Eagle in mitigative actions and the GN in management decisions.

SECTION 4 • METHODOLOGY

The wildlife species that are the focus of the HHS are Caribou, Muskox and Wolverine; however, harvest data on other species, such as Wolf (*Canis lupus*), Arctic Fox (*Vulpes lagopus*), geese and other birds is also collected. The few species in the study were deliberately chosen to make data entry and collection as simple as possible. To support creel surveys, data on fish harvest (i.e., Arctic Char, Lake Trout, Lake Whitefish, and Arctic Grayling) are also collected.

Inuit and non-Inuit residents, at least 16 years of age, are eligible to participate in the harvest survey. Harvest calendars are provided on a household basis, rather than an individual basis, to simplify data entry and collection, and reflect household hunting patterns. The harvest calendar is attractive and consists of local photographs of wildlife and Baker Lake residents (see **Appendix A** for 2021 calendar). Space is provided for each calendar day where harvest details can be documented. A map is provided at the end of the calendar that delineates a 4 km² UTM grid within the Baker Lake and Meadowbank Complex areas. Each grid has a unique code to facilitate recording of information. When calendars are issued, participants or participating households are encouraged to write harvest details (e.g., number of animals, sex, age, and location (i.e., grid code) for the appropriate date on the calendar.

Participants were interviewed in person three times during the year (i.e., June 2021, October 2021, and January 2022) by the harvest study coordinator. During the January 2022 interviews, remaining data from 2021 were collected. The purpose of the interviews is to ensure all harvest data are recorded on the calendars and to collect incidental information to compliment calendar data, including notable Caribou movements, aggregations, and unique observations. Between interview periods, participants were often contacted by phone or social media to encourage recording of harvest data.

Features of the 2021 HHS included: 1) building long-term relationships between participants and researchers; 2) increasing engagement with participants on social media platforms such as Facebook and Instagram; and 3) increasing incentives for participating in the study (e.g., gas vouchers and prizes).

SECTION 5 • HISTORICAL RESULTS

The Baker Lake HTO member list (provided by Ms. Joan Scottie [HTO Board Member] in 2008) consisted of 683 local area hunters/trappers/fishermen (collectively termed ‘hunter’ for the remainder of this memo), a number that has likely changed since then. The member count in 2008 was a highly conservative (i.e., high) estimate of the number of individuals that hunt, trap or fish in the community as the list typically includes entire families. If just the heads of each household are counted, there were 389 potential hunters within the Baker Lake community in 2008. Although this value is still likely conservative (given that many of these individuals do not actively hunt or fish), the number is more comparable to the comprehensive 5-year Nunavut Wildlife Harvest Study (NWMB 2005) in which 336 Baker Lake hunters were contacted and interviewed.

Between 1996 and 2001, 18% of Caribou harvests were estimated to be within 5 km of the AWAR (prior to construction) and 67% of harvests occurred within the RSA (NWMB 2005). In the first year of the HHS study (2007), prior to completion of the AWAR, 34% of harvests were reported within 5 km of the AWAR alignment and 79% were recorded within the RSA. The HHS data (2007 to 2015 and 2019 to 2020) fluctuated between 34 and 43% of reported harvest within 5 km of the AWAR, and between 64 and 85% within the RSA.

In 2008, 296 Caribou were reported as being harvested by Baker Lake HHS study participants. Harvest numbers steadily increased to 685 in 2011, and then decreased to 269 in 2014, the lowest reported harvest in seven years. In 2020, total Caribou harvested was 652, which was slightly more than the 647 reported in 2019. If an average of approximately 10% of all Baker Lake hunters actively participated in the study (5% estimated for 2014), extrapolation of historical HHS values suggests approximately 3,000 to 6,000 Caribou are harvested each year in the Hamlet of Baker Lake. These estimates are in general agreement with historical harvest studies. Specifically, using the upper limit of the standard error in the Nunavut Wildlife Harvest Study, between 2,230 and 3,116 Caribou were harvested each year between 1996 and 2001 (NWMB 2005). Similarly, the Interdisciplinary Systems (IDS) report (IDS 1978) estimated an annual Caribou harvest in Baker Lake of 4,100 during the 1970s.

Based on the NWMB (2005) and HHS results (2007 to 2015 and 2019 to 2020), highest Caribou harvests have occurred in September and October, with a second smaller peak in March and April. The similar pattern between the studies indicates that seasonal hunting preferences have not changed markedly in the last two decades.

Reported harvests of Muskox and Wolverine remained low, precluding any interpretation of potential mine-related effects. Low densities of these species and their general aversion to humans require hunters to hunt well away from the AWAR; however, the presence of the AWAR is thought to have little effect on participant hunting patterns for Muskox and Wolverine. Wolverine harvest reports decreased from a maximum of 15 animals in 2010 to one (1) animal in 2015; however, in 2019 and 2020, reported Wolverine harvests were at an all-time high of 18 and 22 individuals, respectively.

SECTION 6 • 2021 HUNTER HARVEST STUDY RESULTS

6.1 NUMBER OF HUNTERS

The HHS included 55 participants by the end of 2021, which is lower than the 64 participating in 2020 because of several older hunters indicating that “they don’t hunt anymore”. Of the 2021 participants, Caribou harvest data had been collected from 39 participants, which is higher than the 28 participants that reported Caribou harvests in 2015, and slightly lower than the number of hunters reporting harvests in 2019 (42) and 2020 (43).

Based on the previous discussion of total numbers of hunters in the Hamlet of Baker Lake (**Section 5 Historical Results**), there were 389 potential hunters within the Baker Lake community in 2008. The number is comparable to the comprehensive 5-year Nunavut Wildlife Harvest Study (NWMB 2005) in which 336 Baker Lake hunters were contacted and interviewed. Discussions with Baker Lake HTO members in 2019 suggest the total number of hunters is over 300. Given the historical and current number of hunters in Baker Lake, an estimate of 300 to 350 active hunters is used in this analysis. Based on these numbers, the 39 hunters reporting Caribou harvest in 2021 conservatively represent from 11 to 13% of total hunters in the community.

6.2 DISTRIBUTION OF HUNTING

Figure 6.1 shows the distribution of Caribou harvest within the HHS data collection area. Hunting is concentrated in the vicinity of the Hamlet of Baker Lake and along the AWAR to approximately KM 85. Limited harvests were reported along the Thelon River system to Aberdeen Lake, and along the northeastern shore of Baker Lake. Annual variation in harvest location and intensity is attributable to numerous factors. For instance, many hunters have stated during informal discussions that they have a ‘favorite’ hunting area that they frequent each year. Some hunters have stated that they prefer hunting in ‘convenient’ locations, whereas other hunters prefer remote locations well away from frequented areas. A percentage of hunters also enjoyed partaking in long distance hunting trips over multiple days.

Between 1996 and 2001, 18% of Caribou harvests were estimated to be within 5 km of the AWAR (prior to construction) and 67% of harvests occurred within the Meadowbank RSA (NWMB 2005). In the first year of the HHS study (2007), prior to completion of the AWAR, 34% of harvests were reported within 5 km of the AWAR alignment and 79% were recorded within the Meadowbank RSA (see **Table 6.1**). The HHS data (2007 to 2015 and 2019 to 2020) fluctuated between 34 and 54% of reported harvest within 5 km of the AWAR, and between 64 and 85% within the Meadowbank RSA. The 2021 HHS data indicated that 43% of reported harvest occurred within 5 km of the AWAR, and 71% occurred within the Meadowbank RSA (see **Table 6.1**). As was the case in other years, threshold levels of 20% set for monitoring the effects of the Meadowbank mine development (note – does not include the Whale Tail project, which was approved under a separate permit with a different effect assessment) on the distribution of Caribou harvest were not exceeded (see **Figure 6.2**).

Table 6.1: Caribou Harvest Distribution along the AWAR and within the Meadowbank LSA and RSA (1996 to 2001 [NWMB], and 2007 to 2015 and 2019 to 2021 [Baker Lake HHS]).

Study	Participation Rate within 5 km of AWAR (% of total hunters)	Average Caribou Harvest within 5 km of AWAR per Participant	% of Annual Harvest within 5 km of AWAR	% of Annual Harvest within Meadowbank LSA	% of Annual Harvest within Meadowbank RSA
NWMB 1996 to 2001	n/a	n/a	18	7	67
Baker Lake HHS 2007	17 (49%)	4.8	34	12	79
Baker Lake HHS 2008	16 (94%)	6.9	37	28	73
Baker Lake HHS 2009	27 (75%)	7.9	36	20	78
Baker Lake HHS 2010	33 (89%)	7.3	38	22	73
Baker Lake HHS 2011	40 (85%)	7.1	42	25	74
Baker Lake HHS 2012	31 (67%)	5.6	35	20	80
Baker Lake HHS 2013	38 (86%)	4.8	43	27	85
Baker Lake HHS 2014	19 (70%)	5.7	40	28	83
Baker Lake HHS 2015	24 (67%)	6.9	54	34	84
Baker Lake HHS 2019	40 (95%)	5.4	34	22	64
Baker Lake HHS 2020	34 (79%)	5.8	30	19	62
Baker Lake HHS 2021	34 (87%)	6.6	43	32	71
Average (2007 to 2021)	29 (79%)	6.2	39	24	76

In 2021, three (3) Caribou were harvested within 5 km of the WTHR, which compares to no reported harvest during the NWMB harvest study and five (5) Caribou harvested in 2019 (no harvests were reported in 2020) (see **Table 6.2**). Overall harvest numbers were too low to determine whether harvests have increased following construction of the WTHR. Within the Whale Tail RSA (note – overlaps with the Meadowbank RSA), a total of 48 harvests were reported in 2021, which is above the average across the first 11 years of the study but lower than reported harvests in 2011 (103 Caribou), 2015 (53), and 2019 (85). Given the low numbers of reported harvests close to the WTHR and the prohibition of the public from the WTHR, it is unlikely that the presence of the road has resulted in increased harvest.

6.3 MAGNITUDE OF HUNTING

In 2021, a total of 513 Caribou were reported as being harvested by 39 participants in the Baker Lake HHS, which includes harvests in the Meadowbank and Whale Tail study areas (see **Table 6.3**). Given that the 39 hunters represent an estimated 11 to 13% of the Baker Lake hunting community (see **Section 6.1**), the total estimated number of Caribou harvested in 2021 ranged from 3,946 to 4,664 animals, which is lower than estimates in 2019 and 2020. This estimate is very likely conservative (i.e., high) since the Baker Lake HHS targeted known hunters in the community with some known to be particularly successful.

Figure 6.2: Percent of Caribou Harvest within the Meadowbank RSA from 2007 to 2015 (Years 1 to 9), and 2019 to 2021 (Years 10 to 12) Compared to Baseline and Threshold Levels.

Table 6.2: Caribou Harvest Distribution along the WTHR and within the Whale Tail LSA and RSA (1996 to 2001 [NWMB], and 2007 to 2015 and 2019 to 2021 [Baker Lake HHS]).

6.4 SEASONAL DISTRIBUTION AND TIMING OF HUNTING

Based on the NWMB (2005) and inclusive Baker Lake HHS results (2007 to 2015; 2019 to 2021), highest Caribou harvests have occurred in September and October, with a second smaller peak in March and April (see **Figure 6.3**). The similar pattern between the studies indicates that seasonal hunting preferences have not changed markedly in the last decade. More details on the seasonal timing of harvest in 2021 can be found in **Figure 6.4** (i.e., numbers of animals harvested, numbers of participants, and average number of animals harvested by participant by month) and **Figure 6.5** (i.e., Caribou harvest numbers by season and proximity to the access roads).

The seasonal distribution of hunting is illustrated in **Figure 6.1**, which includes all 2021 results, and **Figures 6.6a to 6.6d**, representing the spring, summer, fall and winter Caribou seasons outlined in the TEMP. In spring, overall Caribou hunting was generally low with hunting occurring primarily in the Whitehills Lake area (**Figure 6.6a**). During the summer, Caribou were harvested across a larger area but particularly along the AWAR around Km 85, near the Hamlet of Baker Lake, and along the Thelon River to Aberdeen Lake (**Figure 6.6b**). Two Caribou were harvested near the WTHR in the summer (**Figure 6.6b**). In the fall, hunting was much more concentrated along the AWAR north of Whitehills Lake, around the Prince River, and along the northern shore of Baker Lake (**Figure 6.6c**). Unlike 2020, no fall Caribou harvests were reported along the Kazan River south of Baker Lake. One Caribou was harvested near the WTHR in the fall (**Figure 6.6b**). In winter, fewer Caribou were hunted along the AWAR (**Figure 6.6d**). Successful hunters were those that travelled further afield by snowmobile (e.g., northwest of Whitehills Lake and along the Thelon River to Aberdeen Lake).

6.5 OTHER WILDLIFE SPECIES

There were only two reported harvests for Muskox in 2021, which precludes any interpretation of potential mine-related effects. Surprisingly, one Moose (*Alces alces*) was also reported as being harvested in 2021, but this was outside of the study area. Moose in the Baker Lake area are well north of their known range. Wolverines (total of 20 in 2021 – the second highest yearly tally to date) were hunted close to Baker Lake, in the Whitehills Lake area, and along the Thelon River to Aberdeen Lake (see **Figure 6.7**). Wolves (total of 26 in 2021; significantly lower than the 88 reported in 2020) were either harvested close to Baker Lake or in the Aberdeen Lake area (**Figure 6.7**). In general, relatively low densities of Wolves and their general aversion to humans requires hunters to hunt well away from the AWAR. In 2021, the presence of the AWAR may have had some influence on participant hunting patterns for Muskox and Wolverine.

Arctic Fox (total of 5 in 2021; compared to 11 in 2020) was primarily trapped in the vicinity of Baker Lake, while Red Fox were harvested west of Baker Lake and west of Third Portage Lake (**Figure 6.8**). One Grizzly Bear was taken outside of the study area. Birds (e.g., goose, duck, ptarmigan etc.) were reported as being collected primarily on an island southeast of Baker Lake (**Figure 6.9**).

SECTION 7 • 2021 CREEL SURVEY RESULTS

7.1 NUMBER OF FISHERMEN

The number of fishermen reporting successful fishing trips in 2021 was 27, which is higher than the average of 23 fisherman from 2007 to 2015 and in 2019 to 2020 (11 years), and the highest number of fisherman reporting success since 2012. The highest numbers of fisherman reporting success in 2021 were in May and June period (see **Table 7.1**) (see **Section 7.4 Magnitude of Fishing**).

Table 7.1: Number of Fisherman in the Baker Lake who have Recorded Fishing Success by Year and Month.

Year	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
2007			4	6	7	1	1		1			
2008	1	1	2	6	6	6	4	3			2	1
2009	2	2	5	10	9	9	9	6	1	8	2	2
2010			6	13	18	17	13	4	2	2	3	1
2011	1	3	6	15	21	18	9	6	2	9	9	5
2012	3	1	1	7	7	18	12	4	3	9	7	3
2013			2	5	4	11	9	1		2	1	1
2014	2	1	1	4	6	3	4	2		2	2	2
2015	1	1	1	2	9	8	6	2		3	4	2
2019	1	2	3	12	14	15	7	3	1	1	8	4
2020				1	6	9	9	5	1	4	3	
2021	1		3	3	15	15	3	4	1	1	4	
Total	12	11	34	84	122	130	86	40	12	41	45	21

7.2 COMPOSITION OF CATCH

The most common fish species captured, Lake Trout, represented 67% of the total catch in 2021, which was the same as in 2020 but higher than the average of 55% from 2007 to 2015 and 2019 to 2020 (see **Table 7.2**). Lake Whitefish were also captured at reasonably high numbers.

Table 7.2: Total Number of Fish Caught between 2007 and 2015, and 2019 to 2021.

Species	2021	2020	2019	2015	2014	2013	2012	2011	2010	2009	2008	2007	Total
Arctic Char	54	75	89	41	22	96	24	113	103	117	24	3	632
Arctic Grayling	1			29			1	1	3	1			35
Lake Trout	481	219	900	370	353	490	1,014	1,710	860	525	825	210	7,257
Lake Whitefish	184	32	1573	1386	651	50	471	460	326	51	192		5,160
Fish Species	1	2	119										119
Totals	721	328	2,681	1,826	1,026	636	1,510	2,284	1,292	694	1,041	213	13,203

7.3 DISTRIBUTION OF FISHING

Fishing trips, regardless of success rate, did not generally occur beyond the immediate areas of Baker Lake, Whitehills Lake, and along the lower AWAR (see **Figure 7.1**). Note that the Whale Tail study area is excluded from **Figure 7.1** because no fishing occurred in this area. Some fishing occurred along the Thelon River system and associated lakes (**Figure 7.1**) during the summer when these areas can be accessed by boat. Results indicate that study participants are less willing to travel long distances to catch fish, regardless of AWAR access, likely due to the abundance of fish near the Hamlet of Baker Lake.

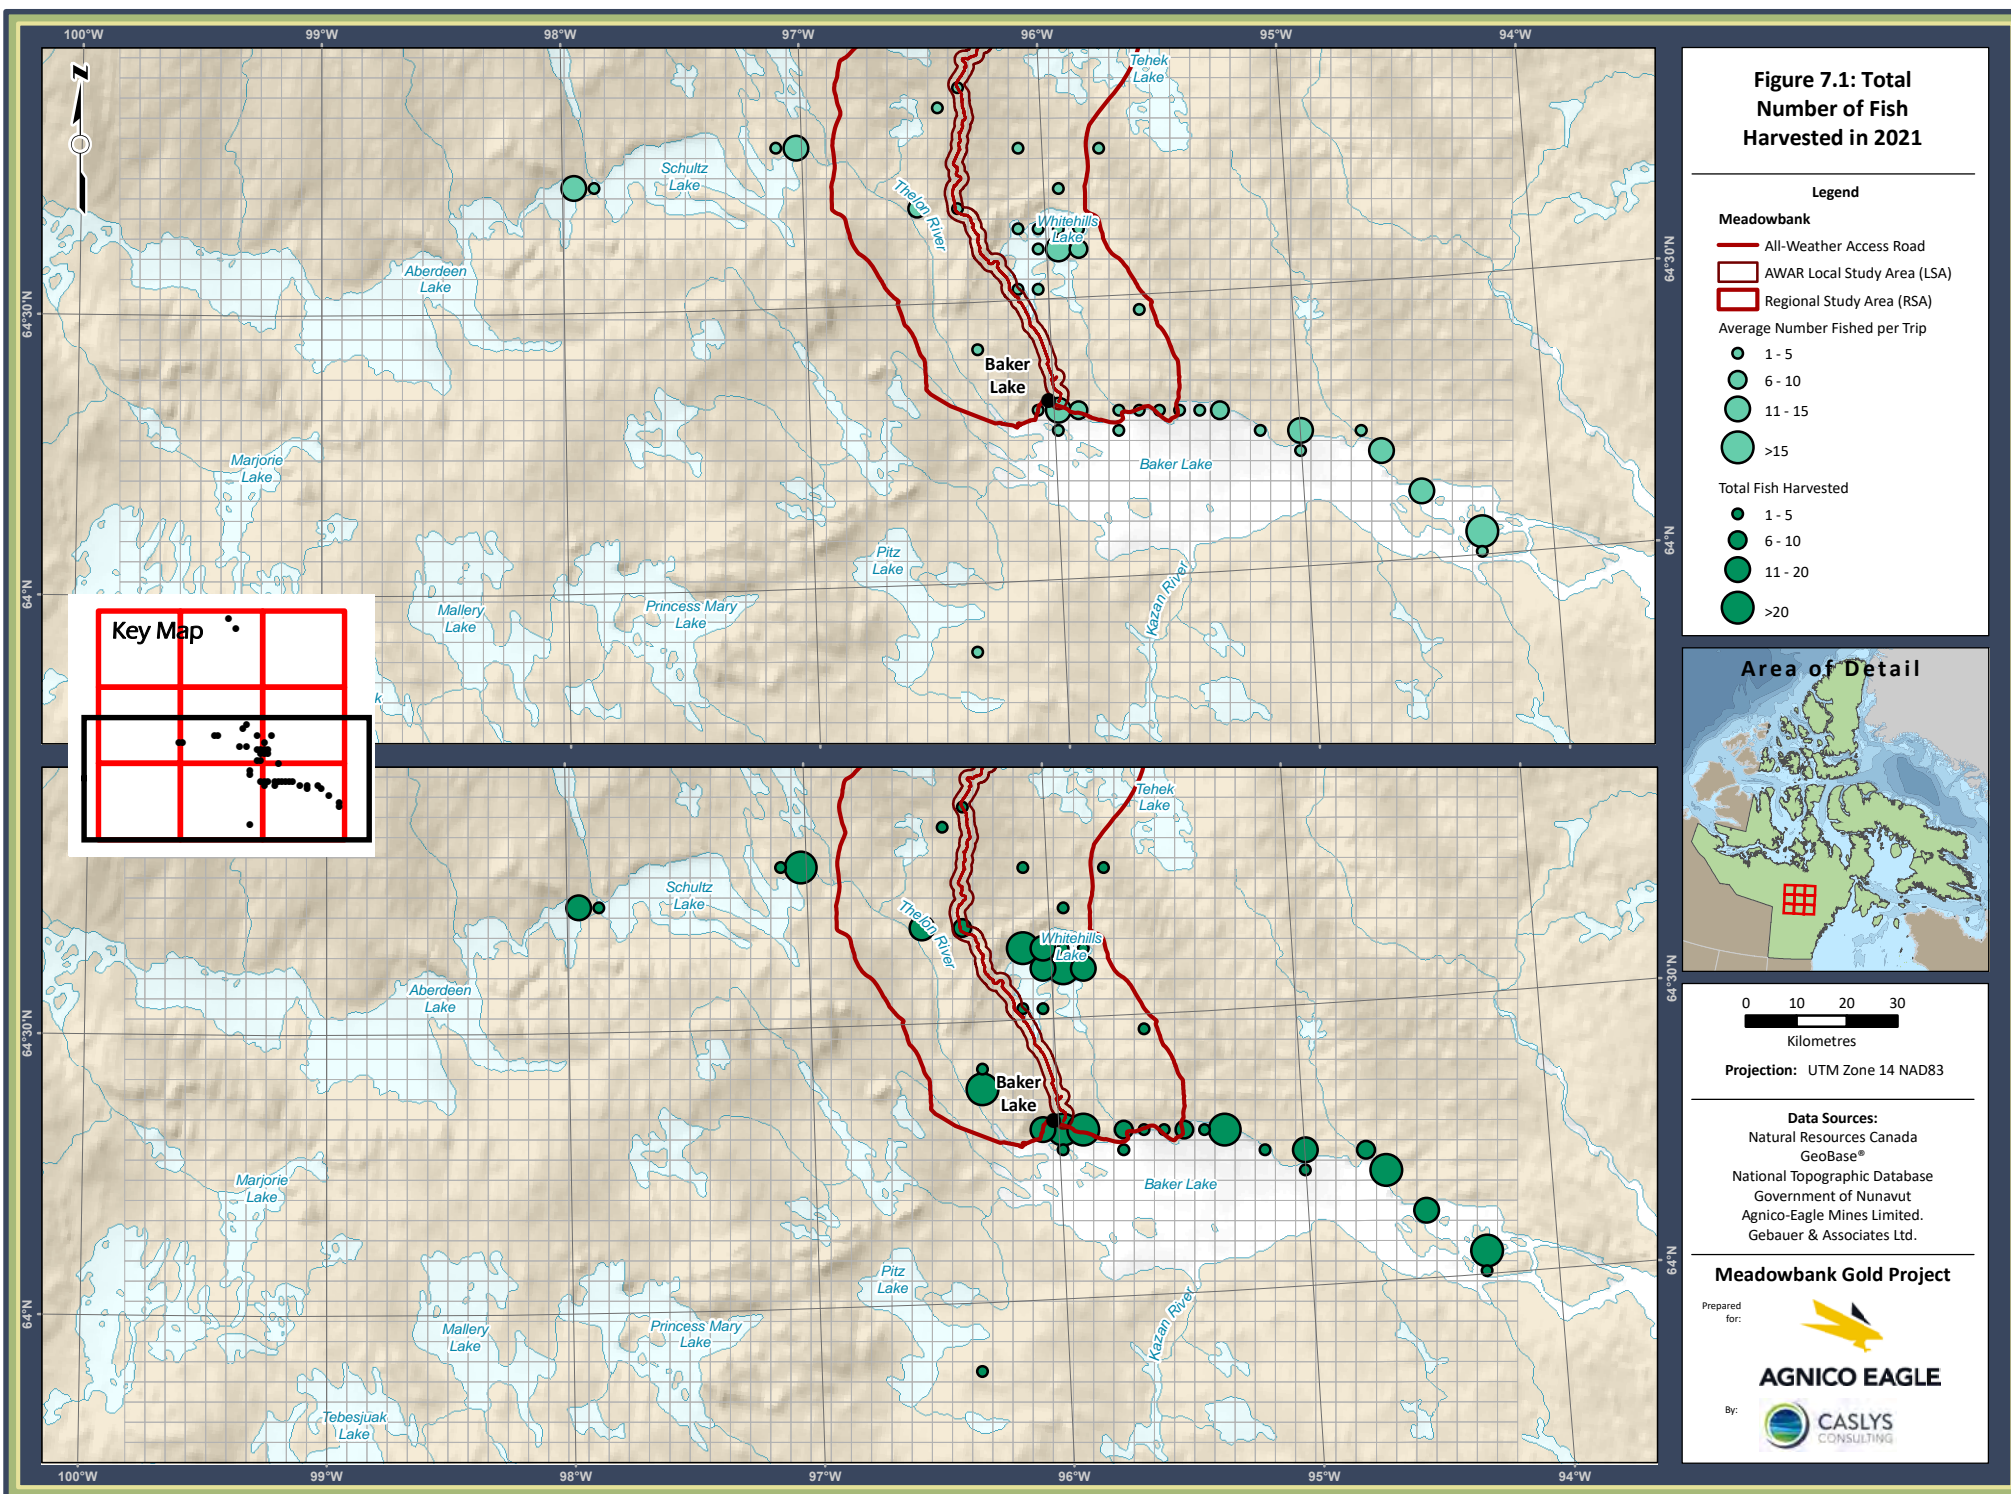

7.4 MAGNITUDE OF FISHING

The average number of fish harvested per fisherman in each month was highest in November with lower averages in the summer months (**Figure 7.2**). In 2021, the most captured fish species, in order of abundance, were Lake Trout, Lake Whitefish and Arctic Char (see **Table 7.3**). Higher numbers of Lake Trout and Lake Whitefish were reported as being caught in 2021 compared to 2020, which is either due to higher abundance and/or increased effort.

7.5 SEASONAL TIMING OF FISHING

In 2021, fishing periods with the most active fisherman was from May to June (see **Table 7.1**). The periods with the most fish caught included the summer months (especially May and June), which reflects the high number of Lake Trout caught by fisherman heading out on the land after ice melt, and November (**Figure 7.3**). This trend can be observed in the overall trends from 2007 to 2015 and 2019 to 2020 (**Figure 7.3**).

Figure 7.1: Total Number of Fish Harvested in 2021

Figure 7.2: Average Number of Fish Caught per Participant in 2021 and the Minimum and Maximum Range from 2007 to 2015 and 2019 to 2020.

Figure 7.3: Seasonal Trends in Fishing in the Baker Lake Area from 2007 to 2015, and 2019 to 2021.

SECTION 8 • ACCURACY OF IMPACT PREDICTIONS

Table 8.1 provides a summary of the impact predictions identified in the original TEMP (Cumberland 2006) and the updated June 2019 version (Agnico Eagle 2019). The 2021 HHS data were compared to the impact prediction thresholds to evaluate adherence to the impact predictions and the provision of adaptive management, as either a necessary or proactive measure. No thresholds were surpassed in 2021.

Table 8.1: Accuracy of Impact Predictions – Baker Lake HHS

Potential Effect	Threshold	Threshold Exceeded (2021)	Adaptive Management Implemented	Status
Meadowbank All-Weather Access Road				
Hunting by Baker Lake Residents	The AWAR will not result in significant changes in the spatial distribution, seasonal pattern, or harvest levels of Caribou kills by Baker Lake hunters. Changes will not exceed 20% of historical harvest activities within the RSA	NO (71% of harvest in RSA in 2021 compared to 67% baseline; average of 76% of harvest within RSA since 2007)	Future discussion with HTO and GN representatives required to identify management options	HHS Creel Survey
Whale Tail Haul Road				
Hunting by Baker Lake Residents	No change in harvest	NO (Only 3 harvests recorded within 5 km of the Whale Tail Haul Road; harvests within the WTHR RSA were lower than some other years, including pre-construction)	None required. Access by hunters is restricted in the growing season and very limited hunting occurs in the winter.	HHS Satellite-collaring Program

SECTION 9 • MANAGEMENT RECOMMENDATIONS

The Baker Lake HHS and Creel Survey should be continued on an annual basis to monitor the hunting and fishing patterns of Baker Lake residents, and the potential effects of the Meadowbank Complex Mine. Meetings with participants every four months (3 times/year) in 2022 are particularly important in maintaining contact, building relationships, expanding the study, and collecting good harvest data. Participation rates can be maintained by continuing to use social media platforms such as Facebook and Instagram, expanding connections on these platforms, ensuring that all participants are visited during the three scheduled field visits, and continuing with distribution of the well-received year-end prizes while in the community. An effort should be made to bring on younger participants in 2022 to replace the attrition of older hunters in 2021.

How to Use the Baker Lake Harvest Calendar

Agnico Eagle Mines Ltd., in cooperation with the Baker Lake Hunters and Trappers Organization (HTO), want to understand hunting and fishing patterns by Baker Lake residents. Specifically, we want to understand how the Meadowbank and Whale Tail Gold Project, located north of Baker Lake, might change traditional harvesting patterns. To ensure that traditional hunting and fishing activities are not negatively affected, we have developed this calendar where participants can record harvest information throughout the year.

Near the back of the calendar is a page that shows the animal and fish species that are included in the study. Please write down the species, number, sex, and location of animals or fish that you have harvested on each date on the calendar. When writing down the location, please use the XY coordinate system provided on the nine maps at the back of the calendar.

For example, if you harvested a male caribou on January 16th on Big Hips Island you would write down “1 male caribou, AF19” in the January 16th square of the calendar.

You will also be visited or contacted by the hunter harvest coordinator occasionally throughout the year. The coordinator's job will be much easier if you write down your harvest information in the calendar as soon as possible.

Please return the calendar to the Agnico Eagle office in Baker Lake at the end of the year or give the calendar to the coordinator when he visits in January. Although each participant will receive a gift expressing our thanks, a draw will also be held in January for a number of high quality prizes.

Please contact the Baker Lake Harvest Study Coordinator, Dylan White at 1-266-500-4202 if you have any questions. Contacts at Agnico Eagle Mines include the Environmental Coordinator at (819) 759-3555, ext. 4606744.

Background

The purpose of the raptor monitoring program from 2015 – 2019 focused solely on searching for nesting sites located near to, and far from proposed or existing infrastructure. Two surveys were planned for 2020, but on-site logistic precluded a survey during the brood-rearing period. Starting in 2021, twice annual surveys are planned. Monitoring of raptors is outlined in the Agnico Eagle Meadowbank Complex Terrestrial Ecosystem Management Plan (TEMP; Agnico Eagle Mine 2019). The TEMP outlines requirements for avoiding and managing disturbance to nesting raptors, as follows:

- Develop a nest-specific response plan for identified raptor nests within areas of concern to ensure that nesting success is not affected by development activities
- Follow GN-DoE guidelines for avoiding disturbance to raptor nests
- Discourage raptors from establishing nests on artificial structures, pit walls, or other facilities
- Active nest monitoring

In addition, the TEMP also outlines the general monitoring approach, as follows:

- document and map raptor nesting sites (see Project Certificate No. 008 Term Condition 33)
- evaluate the success of mitigation to prevent disturbance to raptors or raptor nests
- estimate project-related disturbance effects.
- develop nesting site-specific management plans for nests within 1.5km of project infrastructure, including minimum “no disturbance” buffers (see Commitment 32).
- In the event of deterrence or removal of a nest, Agnico must contact the Government of Nunavut (GN) and secure the required permits (see Project Certificate No. 008 Term and Condition 36).

The GN provided additional feedback from information provided in 2018 Annual Report, as follows:

- the current monitoring does not have the power to detect and mitigate Project-related effects on raptor nesting success.
- the study design does support analysis that would allow detection of project-related nest failures (e.g., by examining nest success as a function of intensity of project-related disturbance).

Species Descriptions

Peregrine Falcon (*Falco peregrinus tundrius*)

The Arctic peregrine falcon (Figure 1) is medium- to large-sized falcon. It has a dark hood and face with distinct dark malar stripe, cream to white throat, slate-grey back; barred belly, legs, and tail. Long pointed wings, stocky body. Plumage of immature birds brown rather than grey, and the breast is streaked rather than barred. In adults, the cere and orbital ring are yellow, and bluish in immature birds. Compared with gyrfalcons, the peregrine is smaller and less stocky. In flight, the wings of peregrines appear narrower and more pointed. In peregrine falcons, wing tips extend to bottom of the tail when perched, while in gyrfalcons, wing tips extend two-thirds down the length of tail

F. p. tundrius breeds mainly north of the treeline from Alaska east throughout northern Canada to Greenland. It breeds throughout the taiga and tundra wherever suitable nesting habitat and sufficient prey are present. In Nunavut, peregrines appear to have their highest densities in the Kivalliq and Kitikmeot regions. Highest density known is on the western shores of Hudson Bay in the Kivalliq Region.

Figure 1 Peregrine Falcon (male)

F. p. tundrius is a long-distance migrant, wintering mainly throughout South and Central America, but also in southern United States and Mexico. Northern-breeding American and Arctic peregrines are highly migratory (Yates et al. 1988, Schmutz et al. 1991, Fuller et al. 1998), and although fall migration occurs over a broad geographic range (Fuller et al. 1998), Yates et al. (1988) indicated that “separate and distinct autumn migratory populations pass through the east and Gulf coasts” of the United States.

Peregrine falcons usually nests on cliffs and rocky outcrops, but also nest on hilltops, river canyons, rock screes, and on occasion directly on the ground (Court et al. 1988, Ratcliffe 1993). They prefer nesting in locations close to water in south-facing, rugged terrain. Hunting habitat includes rugged coastline areas and rolling tundra that consists of raised beaches, dry tundra, sedge meadows, wetlands, and lakes that are inhabited by a diversity of breeding songbirds and shorebirds.

Peregrine Falcons do not build a nest but make a depression (called a scrape) in the substrate on a cliff ledge. Scrapes are usually approximately 20 cm in diameter and 4 cm deep. Females usually do the majority of incubation, and brooding of small young. Males provision incubating females and provide most of the prey when nestlings are small. Thereafter, females do most of the feeding, beginning to hunt after young are large enough to thermoregulate on their own. Clutch size is typically 3 or 4 eggs in Nunavut. In Rankin Inlet and Igloodik, the median incubation period of the first egg was 36 days, and decreased 1 day for each additional egg. The incubation period of the 4th egg (33 days) was similar to what has been reported elsewhere (Burnham 1983).

The Arctic peregrine falcon is a generalist predator with a diverse diet that includes passerines, shorebirds, ducks, gulls, terns, jaegers, black guillemots, and, when available, collared lemmings, brown lemmings, and Arctic ground squirrels. Bradley and Oliphant (1991) indicated that, around Rankin Inlet, small birds (64% of prey items) represented the greatest portion of prey items, followed by microtine rodents (25%),

large birds (8%), and Arctic ground squirrels (4%). The most important prey measured by percent biomass were large birds (43%), followed by small birds (25%), microtine rodents (18%), and Arctic ground squirrels (15%).

In Nunavut, the earliest documented arrival for Peregrine Falcons is 10 May at a known breeding site near Rankin Inlet. Although arrival timing varies with spring conditions, most sites are occupied during the 3rd week of May. Median laying date in Rankin Inlet (9 June) is typically earlier than Igloodik (15 June) and northern Baffin Island (16 June). Median date of hatching ranges from 14 July at Rankin Inlet to 18 July on northern Baffin Island and 20 July at Igloodik (Jaffre et al. 2015). Birds depart the breeding grounds from mid-September through early October, arriving on the wintering grounds throughout Central and South America in November.

Gyrfalcon (*Falco rusticolus*)

The gyrfalcon (Figure 2) is large with pointed wings, but more rounded and broader than the wings of other falcon species. The tail is relatively long. When perched, wings extend 2/3 down the tail. The body is thick and powerful, particularly in females. Adults have yellow ceres, eye-rings and legs. As in all falcons, the eyes appear black. Three main color morphs occur: black, grey and white. White adults have almost pure white breasts and bellies, with dark wingtips (dipped-in-ink appearance). Grey adults have slate-colored back, with white underparts mottled with gray arrowhead-shaped markings. Dark adults are dark grey overall above and dark-streaked breasts and belly. There is extreme reverse sex dimorphism, with males being approximately 2/3 the size of females (Ferguson-Lees et al. 2001).

Gyrfalcons distribution extends throughout the circumpolar Arctic. Most of the breeding range occurs north of 60°N, but breeding pairs are known to exist as far south as 55°N, mainly along seacoasts in eastern Canada. Many adults remain within the breeding range throughout the year, but some disperse southwards in winter, small numbers reaching the norther. United States (Cade 1982, Poole 1987). Immature birds are much more likely to winter to south of breeding range, and females are thought to disperse more widely, with many males remaining relatively close to breeding territories throughout the year.

Ptarmigan are often cited as the most important prey species by biomass, but Arctic ground squirrel and Arctic hare are also important, as well as small mammals (mice and voles) and other birds (ducks, sparrows, buntings). In central Nunavut, Poole and Boag (1988) identified eleven species of birds and five species of mammals among the prey. Birds accounted for three quarters of the diet, and adult rock ptarmigan were the most common. Arctic ground squirrel and arctic hare made up the bulk of mammalian prey.

Males occupy and defend nesting territories as early as the end of January, with females arriving in mid-March. In Nunavut, laying typically begin in the first week of May with most pairs laying by the end of the second week in May. Nestlings typically hatch in mid-June but hatching can occur throughout June. Nestlings fledge in late July or early August after 7 weeks in the nest. In Nunavut, gyrfalcon usually nest on cliff ledges, ideally beneath sheltering overhang; sometimes nests in trees or on man-made structures. Nests are generally on rock ledges or abandoned rough-legged hawk or common raven nests. Use of alternate nest sites is not uncommon. Pairs do not necessarily attempt breeding every year, depending on food supply. Typical clutch size is 3-4 eggs (Booms et al. 2008) that are incubated for 34-36 days mostly by the female (ca. 80%). The North American population including Nunavut is considered to be stable (Clum and Cade 1994, Kirk and Hyslop 1998). Although low spring temperatures are associated with later arrival at nesting territories in Nunavut (Poole and Bromley 1988), there was no effect on laying dates.

However, (Poole and Bromley 1988) indicated that increased spring precipitation (snow) reduced Frank1reproductive success.

Figure 2. Gyrfalcon (female)

Rough-legged Hawk (*Buteo lagopus*)

The rough-legged hawk (Figure 3) is a medium-large bird of prey, with a small beak, predominantly brown in colour and often mottled. Plumage is highly variable with recognized light and dark morphs. Extensive field experience is required to distinguish between males and females, and between adults and juveniles based on plumage alone. A broad chest band is evident in most plumage variations, and in flight, a dark carpal patch is characteristic in light morph individuals. One or more dark terminal bands appear on the tail. The wing tips are long enough to reach or extend past the tail when the animal is perched. Legs are feathered to feet (Ferguson-Lees et al. 2005).

Widespread throughout North America, breeding from the Aleutian Islands, the interior of Alaska, Yukon, northern Mackenzie, and across Nunavut to northern Labrador and Newfoundland and south to Manitoba and southeastern Quebec. In Nunavut, rough-legged hawks are present over most of the territory except for islands without lemmings (Bechard and Swem 2002).

Regularly hovers, or “kites” while facing into the wind scanning for prey. Soars with wings raised in a slight dihedral (V-shape). It is a diurnal raptor that still-hunts from prominent perching structure on both breeding and wintering grounds. Prey is captured on the ground. Courtship involves soaring and calling, with the male engaged in a flight display of repeated undulating stoops rising upward to mid-air stall. It is gregarious on migration, often travelling in flocks, but small groups or individuals are not uncommon.

Breeding pairs prefer rugged terrain areas with steeper slopes in areas associated with vegetation, and were most likely to nest in large, productive valleys surrounded by high-elevation plateaus (Galipeau et

al. 2016). It is widely distributed in winter, usually found in open habitat such as prairies, plains, coastal marshes, agricultural fields, and airports (Johnsgard and Johnsgard 1990). More common in wintering areas with short growing seasons and low precipitation, with highest densities in the northern United States, Great Basin area, and the western shortgrass prairies (Bock and Lepthien 1976, Bock et al. 1977).

The rough-legged hawk is a small mammal specialist; thus, its breeding activity is generally associated with local abundance of ground squirrels, voles, or lemmings (Hanski 1991, Potapov 1997). It will prey on birds when small mammals are scarce, particularly juvenile passerines and shorebirds, and will resort to consuming carrion (Watson 1986). Usually reproductively mature at 2 years of age. Stick-nests are built soon after arrival on territory, typically on cliffs, bluffs, or on the ground. Clutch size varies (1-7 eggs), depending on food availability, but 3-5 eggs are usual and laid in May. Incubation 31-33 days, provided almost entirely by the female. Nestling period is 35-40 days, and fledglings remain dependent on adults for another 2 weeks. The male provisions the young and the female feeds the young. Pairs show nest site fidelity, and in locations where ground squirrels are entirely absent, they may forgo breeding or have small broods when lemmings are low (Bechard and Swem 2002). Bechard and Swem (2002) indicated that egg-laying date was associated with spring temperatures and snow-free ledges, but Potapov (1997) reported no effect of snow melting date or spring/summer temperatures on number of nesting pairs.

Figure 3. Rough-legged Hawk (male)

Methods

Field Surveys

Structured surveys were conducted from 2015 – 2017, 2019 and 2021 (Table 1). The focus of these surveys was to search known nesting sites for the presence of cliff-nesting raptors. In addition to the structured surveys, favorable habitat was searched opportunistically when ferrying between known sites, camps or

other mine infrastructure and when raptors or signs of site use (e.g., whitewash, orange-colored lichen, and unused nests) were observed. Sites were considered occupied if one or more adults displayed territorial or reproductive behavior (e.g., vocalization and/or flight behavior associated with defense of breeding territory or presence of nest building, nest, or eggs). Locations with partially built or unused nests without detection of breeding aged adults were noted as such (e.g., old stick nest; no birds detected). Raptor monitoring in 2021 involved two helicopter surveys (23 – 30 May, 4 – 8 August), and ground - monitoring of potential nesting habitat (natural cliffs, quarries and borrow pits) along the Whale Tail Haul Road (Meadowbank to Whale Tail) and All Weather Access Road (AWAR; Baker Lake to Meadowbank).

Table 1. Survey effort from 2015-2021 for raptors breeding in the vicinity of the Meadowbank complex.

Hours	12	—	10	10	12	—	—	—	10	—	—	—	12	12

Mapping

Shapefiles for the AWAR, Haul Road, and project footprints were read into R using the `readOGR` function in the `rddal` package and converted to a data frame for `ggplot2` using the `fortify` function. The spatial extent for the mapping exercise was set using the `get_map` function in the `ggmap` package. Maps portraying species-specific nesting sites were plotted using `ggmap`.

Data Analysis

Distance to disturbance

Spatial objects (lines and polygons) describing the project footprint were acquired from Agnico Eagle. Euclidean distances from nesting sites to the nearest spatial object were calculated in R (R Development Core Team 2017) using the `sp`, `rgeos`, and `geosphere` packages.

Occupancy

Although estimation of nesting site occupancy can serve as a metric of population status (MacKenzie et al. 2002, 2003), detection of nesting pairs is imperfect, and estimating the proportion of occupied sites without accounting for detection error can lead to underestimation of true occupancy (Kéry and Schmidt 2008). Occupancy modeling can estimate parameters that influence occupancy, and simultaneously account for imperfect detection (Marsh and Trenham 2008). In any given year, the status of a nesting site is limited to one of only two outcomes: occupied or not occupied. Occupancy modelling estimates the following parameters:

1. initial colonization – the probability that a nesting site is occupied in the first survey year (ψ),
2. colonization – the probability that an unoccupied site becomes occupied between years (ϵ),
3. extinction – the probability that occupied site becomes unoccupied between years (γ); and,
4. detection – the probability that PEFA are detected given that the nesting site is occupied (p).

Nesting site survival is estimated as the reciprocal of extinction (i.e., the probability an occupied site remains occupied between years; $1-\gamma$). In addition, environmental covariates can be added to an occupancy model to test whether they influence the above parameters using a logit link function. Multi-year occupancy was calculated in R (R Development Core Team 2019) using the ‘unmarked’ package. When appropriate, data were standardized (e.g., distance to disturbance was standardized by subtracting the mean from each distance value and dividing by the standard deviation), and then formatted specifically for ‘unmarked’ using the *unmarkedMultFrame* function.

Occupancy among years was analyzed separately for Peregrine Falcons and Rough-legged Hawks (there were insufficient data to estimate occupancy for Gyrfalcons). To do so, the total number of nesting sites was filtered to include only those nesting sites that were occupied at least once between 2015 and 2021 for each species. Model fitting of candidate models (Table 2) was performed using the *colext* function. Akaike Information Criterion (AIC) was used for model selection.

Three candidate models were selected *a priori* to estimate the effect anthropogenic disturbance and time (Table 2). The aim of this analysis was two-fold: 1) to estimate the proportion of occupied nesting sites annually, and; 2) to estimate the trend in nesting site occupancy from 2015 to 2021. Trend in occupancy was estimated using annual occupancy probabilities to calculate average rate of change (λ) at the population level (MacKenzie et al. 2003) where a value <1 indicates population decline and >1 indicates an increase. Initial occupancy and detection probability were set to constant (i.e., 1) time varying (i.e., year), respectively, for all models. Model structure for extinction and colonization varied according to the test for effects (see Table 2).

Table 2. Candidate models

Model structure	Model #	Tests for effect of:
$\psi(1) + \epsilon(1) + \gamma(1) + p(\text{year})$	m0	Null (relative effects of covariates in other models)
$\psi(1) + \epsilon(d2d) + \gamma(d2d) + p(\text{year})$	m1	Distance to disturbance (project infrastructure)
$\psi(1) + \epsilon(\text{year}) + \gamma(\text{year}) + p(\text{year})$	m2	Time (captures effect of missing covariates)

Reproductive success

Over the course of the seven-year period, there were only two years in which more than one survey was completed (2016 and 2021; see Table 1). For this report, estimates of reproductive success are reported as the number of young hatched from a single nesting attempt by a pair of birds, regardless of age at the time they were observed. Because nestling age varied considerably between years and among sites, measures of annual productivity *per se* are expected to be biased high. All nesting sites were assumed to be contained within a unique nesting territory (i.e., no nesting territories were occupied by more than one pair of birds, regardless of the potential for alternative nesting sites within nesting territories).

Results

Mapping

Across six different surveys (see Table 1), 134 locations considered to be typical of raptor nesting habitat were surveyed at least once from 2015 – 2017, 2019, and 2021. Of the 134 locations surveyed (Figure 4), nesting raptors have been detected at 74 nesting sites (Table 10). Peregrine falcons have been documented at 56 nesting sites, rough-legged hawks at 26 nesting sites and gyrfalcons have been documented at nine nesting sites.

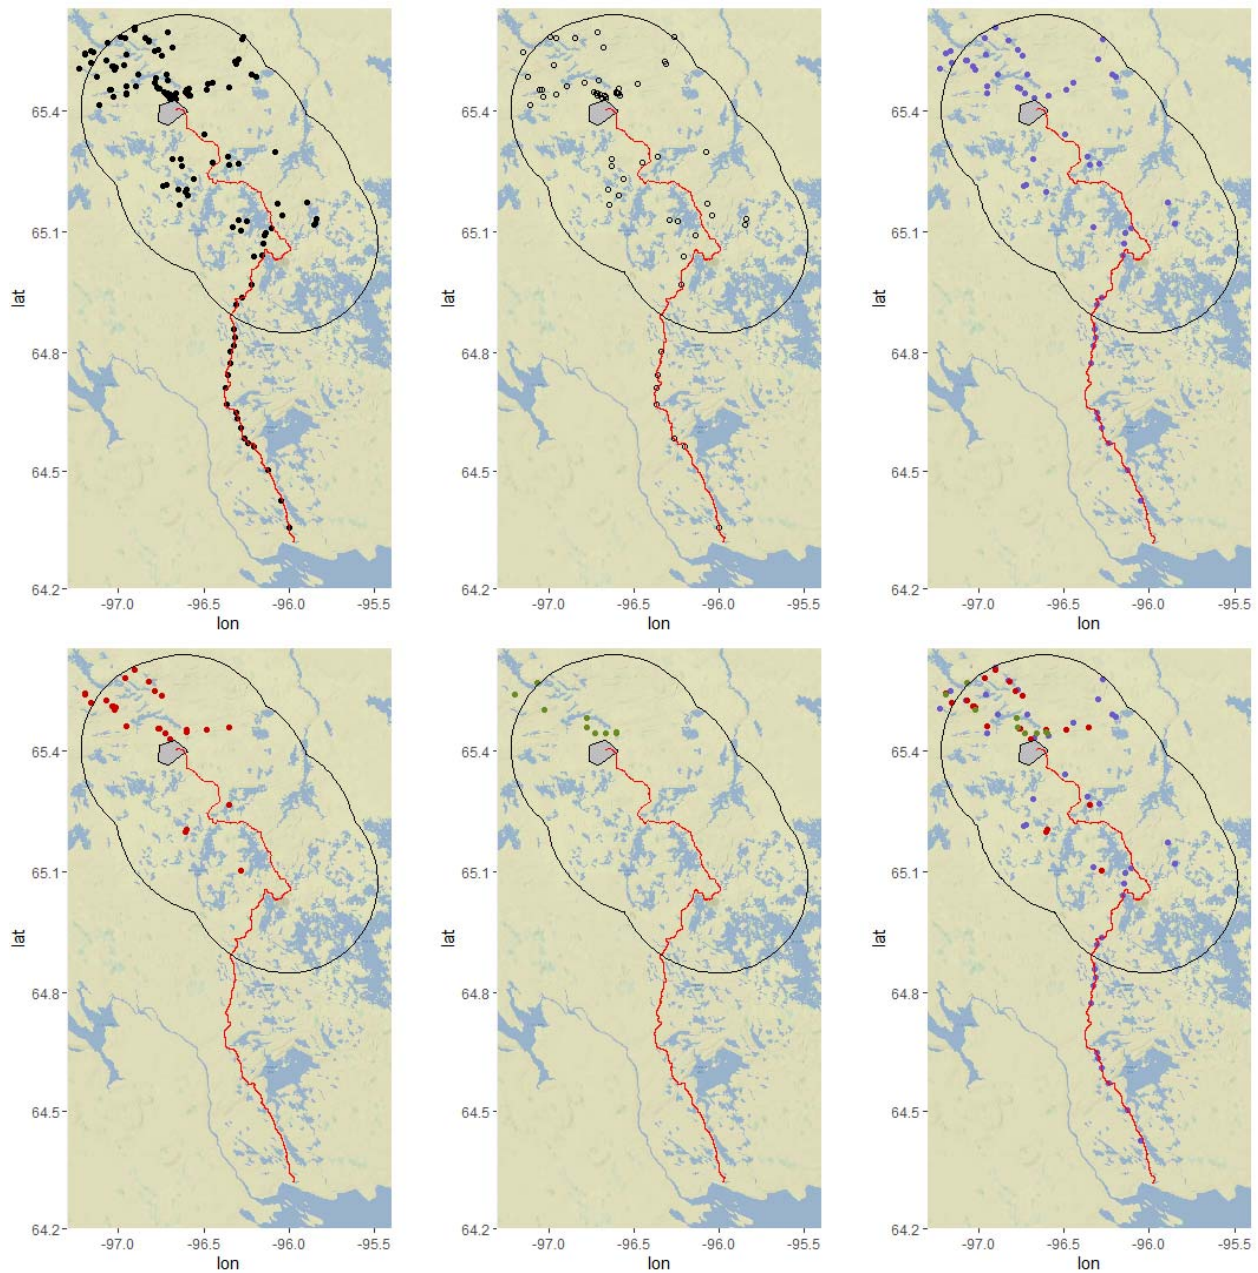

Figure 4. All cliffs surveyed (n=134; top L), cliffs with no record of occupancy (n= 60; top C), PEFA nesting sites (n = 56; top R), RLHA nesting sites (n=26; bottom L), GYRF nesting sites (n=9; bottom C), and all recorded nesting sites combined (bottom R) for the period 2015 – 2021 in the vicinity of the Meadowbank/Whale Tail complex

Distance to Disturbance

Mean distance from known occupied nesting sites to project infrastructure was 9.50 km (SD=8.19 km). Sixteen nesting sites fell within 1.5 km of the AWAR, Haul Road, or Whale Tail Project footprint and are considered candidates for development of a site-specific management plans. Fourteen of the 16 nesting sites are within the 600m limit (500m baseline setback, plus additional 100m setback during the breeding season) identified by the Government of British Columbia (2013) for species with moderate ability to co-exist with human activity. Fifteen nesting sites have been occupied by peregrine falcons, and one nesting site has been occupied by rough-legged hawks. Thirteen of the 15 peregrine falcon nesting sites were in

rock quarries excavated for road building and maintenance, and two were located on natural cliffs. The single rough-legged hawk nesting site located less 600m from the project footprint was located on a natural cliff.

Occupancy

Peregrine Falcons

The top occupancy model included colonization and extinction effects of distance to disturbance, and a year effect for detection (Table 3). However, the delta AIC for the second-ranked null model was 0.53, strongly suggesting that the effect size of distance to disturbance was immaterial, or very low. Using the null model (Table 4), trend in occupancy (Figure 5) was $\lambda = 0.95$ (SE=0.02). The minimum and maximum number of nesting sites sampled in any year was 14 (2018) and 56 (2021), respectively (Table 5). The minimum and maximum number of breeding pairs detected was 7 (2020) and 32 (2016), respectively (Table 5).

Table 3. Model selection based on AIC score for peregrine falcons

Model structure	Model #	Parameters	AIC score	delta AIC	AICwt	Cumltvwt

2020	14	7	4	2	8	14
2021	56	24	3	2	9	14

Figure 5. Proportion of PEFA nesting sites occupied from 2015 – 2021 in the vicinity of the Meadowbank/Whale Tail complex. The proportion observed (open circles with dashed lines) are point estimates without error bars, and do not account for detection error. The proportion estimated (closed circles with solid lines) accounts for detection error and includes standard error bars. Lambda = 0.95±0.02

Rough-legged Hawks

Among the candidate models (Table 6) for rough-legged hawk occupancy, the null model was ranked first (see for parameter estimates). Trend in occupancy (Figure 6) calculated as average rate of change at the population level was $\lambda = 1.25$ (SE=0.25), where a value <1 indicates population decline and >1 indicates an increase (MacKenzie et al. 2003). Although lambda is much greater than 1.0, large standard errors overlapping with 1.0 indicate that trend is almost certainly neither increasing nor decreasing (Figure 6). The minimum and maximum number of nesting site sampled in any year was 0 (2018 and 2020) and 26 (2017 and 2019), respectively. The minimum and maximum number of breeding pairs detected was 0 (2018 and 2020) and 16 (2017), respectively.

Table 6. Model selection based on AIC score for rough-legged hawks

2020	0	0	0	0	0	0
2021	26	9	0	0	0	0

Figure 6. Proportion of RLHA nesting sites occupied from 2015 – 2021 in the vicinity of the Meadowbank/Whale Tail complex. The proportion observed (open circles with dashed lines) are point estimates without error bars, and do not account for detection error. The proportion estimated (closed circles with solid lines) accounts for detection error and includes standard error bars. $\lambda = 1.25 \pm 0.25$

Reproductive Success

Table 9. Estimates of reproductive success for peregrine falcons and rough-legged hawks detected in 2016 and 2021 in the vicinity of the Meadowbank/Whale Tail complex. Values are reported as the number of young hatched from a single nesting attempt by a pair of birds, regardless of nestling age at the time they were observed. Because nestling age varied considerably between years and among sites, measures of annual productivity per se are expected to be biased high.

Year	Peregrine falcons		Rough-legged Hawks	
	2016	2021	2016	2021
Count of occupied nesting sites detected	32	24	12	9
Count of nestlings detected	28	9	20	11
Productivity (apparent)	1.14	0.38	1.67	1.22

Conclusion

This report applies GN-DoE guidelines (Government of British Columbia 2013) to assess potential disturbance to known nesting sites that have been identified over the course of seven survey-years. Agnico Eagle has detected thirteen peregrine falcon nesting sites in rock quarries excavated for building and maintenance of the AWAR. To date there have been no instances of raptors establishing nests on artificial structures along the Haul Road or Whale Tail site.

Monitoring has focused on searching for, documenting and mapping nesting sites for three raptor species (peregrine falcons, rough-legged hawks, and gyrfalcons). Study design was limited to single surveys in some years, which limits estimation of detection error. To address this limitation, starting in 2021, the study design was updated to incorporate multiple surveys annually, and took advantage of the distribution of known nesting sites to monitor occupancy as a function of distance to project-related disturbance.

This report meets Term and Condition 33 by documenting and mapping raptor nesting sites (Figure 4, Table 10). There is no evidence for project-related related disturbance effects for rough-legged hawk occupancy, but occupancy trend for peregrine falcons indicates that the population has declined marginally. This finding may be the result inconsistent monitoring within and among seasons and is consistent with the GN comment in the 2018 Annual Report regarding the potential for insufficient power to detect to project-related effects. There has been no incident requiring permitting for removal of a nest (Term and Condition 36).

The TEMP requires that raptors are deterred from establishing nests on artificial structures, pit walls, or other facilities. However, this has not been done for quarries along the AWAR, except for Quarry 22 and 20, which have become regularly occupied nesting territories. Where occupied nesting sites were detected, mine-related activity within the quarries was restricted. Nesting sites were monitored to minimize disturbance. Nest visits were conducted periodically to conduct egg and nestling counts. Presence of nesting pairs was not made public to minimize disturbance. To fulfill the requirement to develop management and response plans, Agnico Eagle shall update the TEMP in 2022 to include the following: 1) for roadside quarries where work is planned, deterrents will be placed in the quarries in early May prior to arrival on territory; 2) for roadside quarries where no work is planned, regular monitoring shall be conducted to determine occupancy status; 3) for dormant quarries, nesting raptors shall be monitored regularly throughout the breeding season to determine reproductive status (signage shall be placed to identify the presence of breeding raptors and will include a no stopping zone for vehicular traffic).

Improved monitoring and management of these nesting sites can fulfill the requirements outlined in the TEMP, which include active nest monitoring , evaluating the success of mitigation to limit disturbance, and estimating project-related nest failures). In 2022, two specific sites visits are scheduled and will contribute to meeting NIRB Project Certificate Term and Condition.

Table 10. Geographic coordinates (decimal degrees), distance to disturbance (Km) for known nesting sites surveyed between 2015 and 2021. Nesting sites that require management plans are identified.

FLIXWEED (*DESCURAINIA SOPHIA*) RISK ASSESSMENT

1.0 BACKGROUND

Agnico Eagle Mines Limited (Agnico Eagle) initiated a non-native plant monitoring study in 2019 at their Meadowbank-Whale Tail Complex to assess and monitor the potential introduction of non-native plant species, including weeds or invasive species. The results of these surveys have indicated large populations of the non-native plant flixweed (*Descurainia sophia*) are present throughout the Meadowbank-Whale Tail Complex. After three consecutive years of monitoring, the populations appear to be stable, though potentially expanding in size and distribution. The Government of Nunavut (GN) has recommended that Agnico Eagle produce a risk assessment examining:

- the potential for the species to colonise undisturbed habitats beyond the disturbed areas of the Meadowbank-Whale Tail complex;
- the impact of this species on efforts to revegetate disturbed areas of the complex with species and plant communities endemic to Nunavut, as required under term and condition 26; and
- the risk of this species to wildlife such as caribou.

In late 2021, it was proposed by a botanist at the Canadian Museum of Nature (P. Sokoloff, personal communication, September 26, 2021) that the species being classified as flixweed could possibly be the native species, northern tansymustard (*Descurainia sophioides*). Both flixweed and northern tansymustard are very similar in appearance and habitat and therefore fill similar ecological niches. The best way to distinguish the two species is based on the shape of the hairs, visible under magnification. Flixweed has star shaped hairs on the surface of its leaves while northern tansymustard has glandular hairs (Densmore et al. 2001). Because it was too late in the growing season in 2021 to obtain a viable sample for identification, the plant cannot be definitively identified until the next growing season in 2022.

This risk assessment will focus on flixweed as there is much more published literature available to assess its habitat, global distribution, reproduction and potential control methods. Much less is known about the native northern tansymustard other than its preferred habitat and where it has been observed. The risk assessment can be updated when the identity of the species can be confirmed.

2.0 FLIXWEED (*DESCURAINIA SOPHIA*)

General Information

Flixweed is a winter annual, meaning it emerges in fall, overwinters as a rosette, and resumes growth in early spring. The seedlings establish early in the season as low to the ground rosettes which protect the plant from low temperatures and drying winds and is insulated by the snow (Mitich 1996). The plant is greyish green in colour due to minutely branched or forked hairs with alternate, fern like leaves, finely dissected two to three times. Flixweed has a single coarse stem with basal and cauline leaves that are pinnately divided 2 to 3 times (Howard 2003). Its flowers are clustered at the top of the stem with yellow petals. Flixweed is listed as a Tier 3 noxious weed in Manitoba (GoM 2020) and in Alberta flixweed is not regulated under the *Weed Control Act* (2011) and Regulation as prohibited noxious or noxious but is considered a nuisance weed as it is so common and abundant across the province (ABMI 2009). It is not listed as a regulated weed in any other province or territory in Canada.

Habitat/Distribution

Flixweed is an introduced species from Europe and Northern Africa and it was discovered in Canada around 1840 (Best 1977, Hulten 1968, Mitich 1996). Its North American range is widespread from Quebec to Washington, south to Delaware, New York, Illinois, Missouri, Kansas and California (Mitich 1996). It is not known to occur in Nunavut but is present in all other provinces and territories in Canada (FNA 2022).

Flixweed grows in a broad spectrum of environments ranging from cold desert, tundra, alpine to hot desert and dry tropical Hawaiian ecosystems (Kartesz and Meacham 1999). It grows in disturbed habitats, roadsides, waste places, railroad embankments, fields, lawns pastures and deserts (FNA 2022). It is well adapted to dry sites (CABI 2022) which explains why it grows well along gravelly roadsides, quarries, and laydown areas around the Meadowbank-Whale Tail Complex.

Flixweed tends to grow in early successional communities. One experiment in northwest Colorado showed flixweed appearing in the first year after bulldozing the site. The plant biomass peaked after two years following disturbance and declined for the next five years. It was present in only trace amounts in undisturbed adjacent plots (McLendon and Redente 1994). On strip-mined sites in south-central Alaska, flixweed volunteered on revegetated reclamation sites, but was absent by post-treatment year 10 (Elliott et al. 1987). It does not tend to invade natural plant communities (University of Alaska Anchorage 2011) and is therefore perceived to not be a threat to native plant populations (Densmore et al. 2001).

Reproduction

Flixweed is a prolific seed producer, with each plant producing on average 75,000 seeds but is capable of producing up to 700,000 seeds per plant (Mitich 1996). Seeds are spread by wind, vehicles and machinery (Howard 2003) and establish on open soil disturbances (Densmore et al. 2001). Reproduction occurs exclusively by seed (Salisbury 1961); therefore it is important to control plants before they go to seed. However, long-term viability of seeds is reported to be of considerable length in the soil (Salisbury 1961). Buried flixweed seed remained viable for at least 4 years in Alaska (Conn, 1990).

Germination rates of seeds are generally high. Flixweed seed collected in Alberta showed 75% germination after cold storage/stratification (Blackshaw 1991). Germination was still observed after one day in a cow's rumen and after eight weeks in a barley filled silo (Blackshaw 1991). The establishment of flixweed occurs soon after a soil disturbance, however abundance normally declines as perennial species take over (Tannas 2004).

Control Methods

Control of flixweed can be achieved through mechanical treatment and herbicide (University of Anchorage Alaska 2011) however, given the sensitive nature of tundra habitat, the use of herbicides should be avoided. Flixweed has even been shown to be resistant to several herbicides (Heap 2022). Herbicides are also rarely a complete or long-term solution to flixweed management (Bussan and Dyer 1999) because they do not change the conditions that allow infestations to occur (Youtie and Soll 1990).

Flixweed is managed in agricultural settings by fall or early spring cultivation before flowers and seeds have been produced, which physically removes the overwintering rosettes (Best 1977, E-Flora BC 2022). Flixweed does not resprout after removal of aboveground growth (Densmore et al. 2001). For smaller infestations uprooting plants by hand can be effective (Colorado Department of Agriculture et al., 2000).

Some weed species are able to be managed by increasing shade depending on how shade tolerant the species is. Greenhouse trials were able to show flixweed biomass was reduced when light transmission was reduced (Landau et al. 2017). Trials at the Meadowbank-Whale Tail Complex in 2021 included placing geotextile fabric over dense populations to reduce light availability. Results of these trials are pending until an assessment during the 2022 growing season.

Because flixweed is considered a pioneer species, it does not usually persist in late-seral communities and may not require special control measures if native plant cover can be established (Howard 2003). Canopy closure, litter accumulation and/or growth interference from later-successional species tend to exclude flixweed over time (Howard 2003). Because it appears to be largely controlled by successional status, little effort has been spent on researching other controls such as fire, herbicides, mechanical treatments (Howard 2003). Replacement with desirable species and prevention of new infestations is considered the most effective management of flixweed (Howard 2003).

Potential Risk to Wildlife

Although there are studies on the effects of flixweed on livestock, wildlife use of flixweed and other tansymustards is poorly documented. The plants do contain poisonous levels of nitrate (Stephens 1980) and seeds contain poisonous isoallyl thiocyanates and irritant oils; however large quantities must be consumed over time for poisoning to occur (Fishel 2003). Observations of sage-grouse in Nevada showed they grazed most of the early spring forbs in a big sagebrush community but avoided flixweed (Savage 1969). Flixweed is moderately palatable to livestock, although livestock may prefer other tansymustard species. In free-choice trials, cattle in Montana selected western tansymustard (*Descurainia pinnata*) more often than flixweed (Pfister et al. 1990). Further studies are needed to determine the relative importance of tansymustards in animal communities – including barren ground caribou (Howard 2003).

3.0 NORTHERN TANSYMUSTARD (*DESCURAINIA SOPHIOIDES*)

Northern tansymustard (*Descurainia sophioides*) is native to the arctic and subarctic (Mitich 1996). Its habitat is very similar to that of flixweed as it grows on gravel bars, roadsides, parking areas, eroded peat, waste sites, rocky outcrops, mining dumps and disturbed soils (BC CDC 2022, FNA 2022). It is common in the western arctic around settlements and along roads (Aiken et al. 2007). The global range of northern tansymustard is from Hudson Bay to Alaska (BC CDC 2022). Known populations of northern tansymustard have been collected from Baker lake (1983), Rankin Inlet (1974, 1991, and 2001) and herbarium specimens are at the Canadian Museum of Nature (BC CDC 2022).

Because it is a native species in a remote region with little economic purposes, much less is known about northern tansymustard compared to flixweed.

4.0 CONCLUSIONS

Flixweed has shown that it can easily establish in the disturbed habitats in and around the Meadowbank-Whale Tail Complex; however it has yet to be observed in the native tundra. The literature supports this observation that it does not persist in late seral vegetation communities. The vegetation in native tundra is likely sufficient to keep flixweed from establishing. The risk of flixweed colonizing undisturbed habitat at the Meadowbank Complex is low. Additionally, given its ability to establish quickly and overall short-lived persistence to disturbed areas, flixweed does provide some benefit of soil stabilization in disturbed areas to minimize soil erosion and loss.

Revegetation of disturbed areas will likely initially include populations of flixweed as it is an early pioneer species. Once native plant cover can be established, these populations should begin to decrease with minimal control interventions.

Although the risk to caribou and other wildlife of foraging on flixweed is unknown, it is likely that large quantities need to be consumed for toxic effect. Further, surveys of non-native species at the Meadowbank-Whale Tail Complex should monitor for non-native plant species that have been grazed by wildlife.

If the flixweed species is identified to be the native northern tansymustard, these risks will need to be re-evaluated to determine, which if any are applicable.

5.0 CLOSURE

We trust that this report provides the information you require at this time. Please contact the undersigned if there are any questions or clarification is needed.

EXECUTIVE SUMMARY

The Meadowbank Complex, owned and operated by Agnico Eagle Mines Limited (Agnico Eagle), is located on Inuit Owned Land (IOL) and includes the Meadowbank Gold Mine (the Project) approximately 90 km north of the Hamlet of Baker Lake, and the Whale Tail Pit Project located approximately 150 km north of the Hamlet. A 108 km All Weather Access Road (AWAR) connects the Meadowbank Gold Mine to Baker Lake, and the 72 km Whale Tail Haul Road (WTHR) connects the Meadowbank Gold Mine to the Whale Tail site. During spring and fall migration, Lorillard caribou, along with smaller numbers of Wager Bay and Ahiaik caribou occur in the Project area, regularly crossing through the Project site, AWAR, and WTHR.

As part of the Nunavut Impact Review Board (NIRB) Project Certificates #004 and #008, Agnico Eagle is required to study and report on the effects of the Project on caribou. The Agnico Eagle Terrestrial Ecosystem Management Plan (TEMP; 2019) includes behaviour monitoring for caribou.

During 2020, Agnico Eagle retained ERM Consultants Canada Ltd. (ERM) to update the field protocols used for behaviour monitoring. ERM adapted standard methods for caribou behaviour monitoring developed by the Government of Northwest Territories Department of Environment and Natural Resources (GNWT ENR). Following the first year of data collection in 2020 and comments from the Terrestrial Advisory Group (TAG) reviewers, the Government of Nunavut (GN), and Kivalliq Inuit Association (KivIA), the protocols were updated for the 2021 season to improve the quality of the data collected.

Field surveys were conducted primarily during spring and fall migration in 2020 and 2021 by the Agnico Eagle environmental technicians. These technicians were trained and were dedicated to conducting behaviour surveys. Each survey lasted 30 minutes, with scan samples conducted every three minutes.

The behaviour monitoring data from 2021 were combined with data from 2020, and all results outlined in this report use both years, unless otherwise stated. The program and combined data resulted in several key findings:

- The standard monitoring protocols adapted from the GNWT ENR worked well at the Project site.
- 134 surveys were conducted in 2021, compared to 116 in 2020; 114 surveys occurred during spring migration from March to May, 15 occurred during calving and summer from June to August, and five occurred during fall migration from September to December.
- Caribou mostly exhibited the non-response behaviours of standing, laying, feeding, and walking.
- Observations were well distributed across a range of caribou group sizes from 1 to 2 individuals to >1,000.
- Larger groups of caribou tended to be recorded further from the road. Only two groups larger than 100 individuals were recorded within 100 m of the road at the start of the survey, both in 2021.
- Caribou group size was not linked to response behaviour or walking behaviour in statistical analyses.
- Statistical analysis indicated that there is a trend for caribou at greater distance from the road (>1,000 m) to have a lower proportion of response behaviours (alert and running) than caribou within 100 m of the road.
- Approximately 70% of the surveys included a disturbance event; typically, haul traffic and light trucks from the mine, and occasionally all-terrain vehicles (ATVs) from Baker Lake on the AWAR for travel and harvesting.
- Following a disturbance event, the proportion of response behaviours in a group of caribou was significantly higher, but generally returned to baseline behaviours within one or two sampling intervals (i.e., three or six minutes).

- In response to comments from the KivIA, the behaviour of “walking” was investigated for whether it may be an “alert” behaviour instead of a non-response behaviour, however, disturbances did not statistically affect the proportion of caribou walking.
- Surveyors conducted special 90-minute surveys during convoys to assess whether the response to convoys was similar to that of other vehicles. Caribou responded similarly to convoys but possibly for longer than for other vehicles. More convoy surveys are needed to analyse the data statistically.
- During periods when large groups of caribou are present, the AWAR and Haul Roads are closed following a decision tree in the Meadowbank Mine TEMP, reducing the potential to record interactions between vehicles and caribou. Road closure status did not affect behaviour in the statistical analysis, possibly due to it having less explanatory power than the other variables included.
- Groups of caribou were observed on both the east and west sides of the road in all seasons, but were more commonly observed on the west side during spring migration (a.k.a. upstream of the dominant direction of travel). Statistical analysis found that side of road and season did not affect response behaviour (alert/running), but that caribou were significantly more likely to be walking on the upstream side of the road. The dominant behaviour on the downstream side was feeding or laying down.

The updates applied to the survey protocol in 2021 used feedback from the first year of data and analysis, and were helpful in improving the overall quality and accuracy of the data. Even with some changes to the protocol between 2020 and 2021, the trends in the results were highly consistent between the two years of data. This increases the confidence that trends are repeatable year to year. Overall, the results of the statistical analysis provided support for the key hypothesis that caribou tend to respond to disturbances, particularly when they are close to the road. However, the analysis also found that disturbances did not have a detectable effect on caribou behaviour after three to six minutes. Additional data collection in fall and during convoys would bolster the sample size and improve the likelihood of detecting statistically significant effects.

1. PROJECT OVERVIEW

The Agnico Eagle Mines Ltd. (Agnico Eagle) Meadowbank Gold Mine (the Project), located in the Kivalliq Region of Nunavut (Figure 1-1), received a Project Certificate (#004) from the Nunavut Impact Review Board (NIRB) in 2006. The adjacent Whale Tail Pit Project received a Project Certificate (#008) from the NIRB in 2018, which was amended in 2020. The Project Certificates, and subsequent Water Licenses (#2AM-WTP1830), GN and CIRNAC Land Lease, and KivIA Production Lease, allowed development of five gold deposits in the 11 years since the start of operations at the Meadowbank Gold Mine and the first phase of the Whale Tail satellite deposit. This has included construction of a gold mine and ancillary facilities including an All Weather Access Road (AWAR), Whale Tail Haul Road (WTHR), barge unloading facilities, lay-down area, and a fuel tank farm near the Hamlet of Baker Lake.

The Meadowbank Gold Mine is located approximately 90 km north of the Hamlet of Baker Lake. Mining has ceased at Meadowbank, but the site hosts accommodation, an active mill, and ancillary mechanical, maintenance and vehicles. The Whale Tail Pit Project, located approximately 150 km north of the Hamlet, is an open-pit, truck-and-shovel mine operation and will produce an estimated 19 M tons of ore. Ore is hauled from Whale Tail to the Meadowbank Gold Mine for milling on the WTHR.

Studies of caribou behaviour were conducted during spring migration, summer, and fall migration in 2020 and 2021 at the Meadowbank Gold Mine, AWAR, and WTHR to monitor for potential Project effects on caribou.

1.1 Project Terms and Conditions and TEMP

Under the NIRB Certificate #008 for the Whale Tail Project, Term and Condition 28 requires the Project to have a Terrestrial Ecosystem Management Plan (TEMP):

(NIRB #008; T&C 28) The Proponent shall maintain a Terrestrial Ecosystem Management Plan (TEMP) throughout all phases of the Project. The Plan shall include detailed monitoring, mitigation, and adaptive management measures for wildlife, with consideration for each Project activity predicted to affect wildlife, and with inclusion of specific triggers for mitigation and adaptive management intervention. The TEMP shall demonstrate consideration for all relevant commitments made by the Proponent throughout the Nunavut Impact Review Board's review of the Project.

The Meadowbank Division TEMP (Agnico Eagle 2019) is designed to meet this condition. The TEMP includes a survey program for caribou that records caribou behaviour in response to various disturbances.

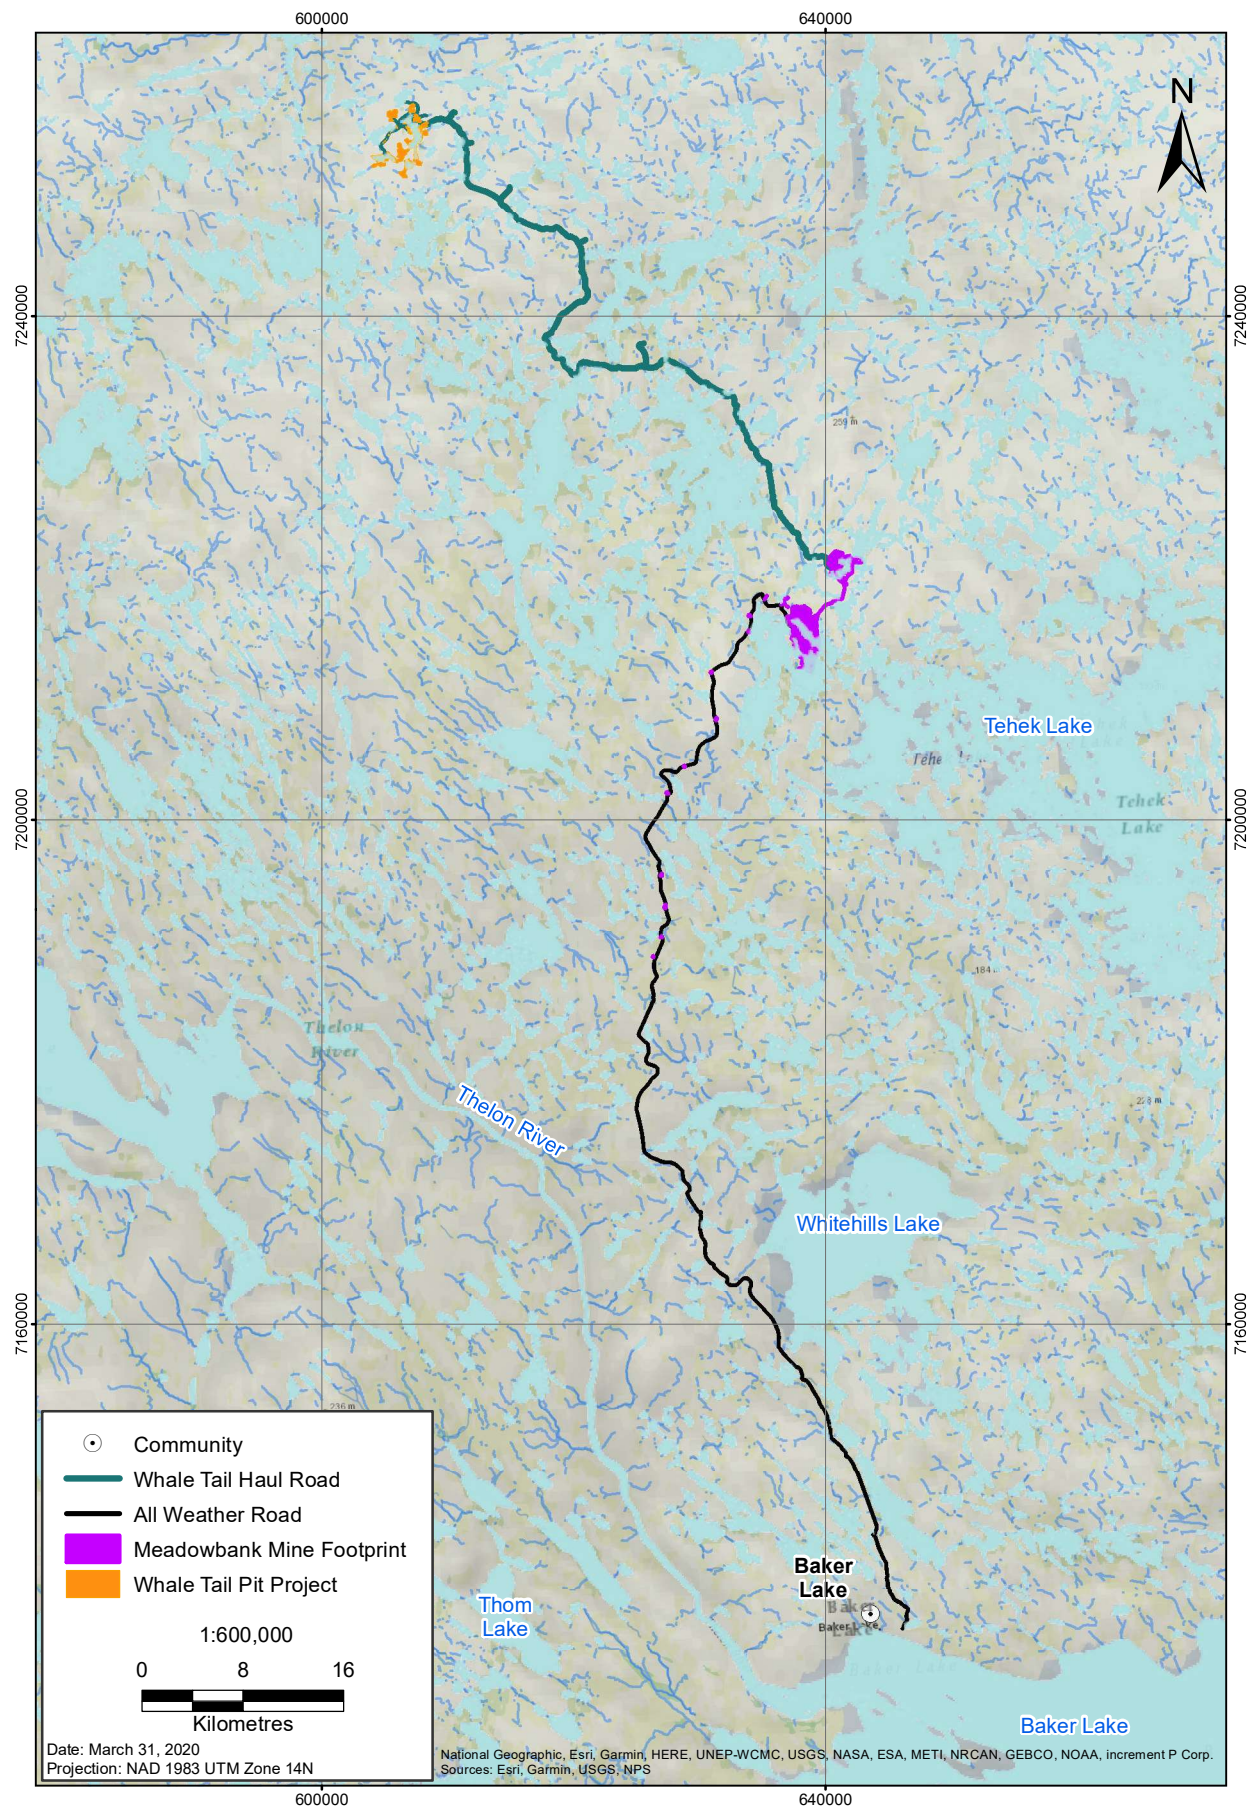

Figure 1-1: Location of Meadowbank Gold Mine and Whale Tail Pit Project

2. STUDY OBJECTIVES

Based on guidance from the TEMP, the overall objective of the caribou behaviour monitoring program is:

- To determine if caribou activity budgets change with distance from the mine, and to document caribou response to stressors.

The detailed objectives of the 2020 and 2021 combined study were:

1. To conduct a study using the Government of Northwest Territories Department of Environment and Natural Resources (GNWT ENR 2017) behaviour survey methodology at the Project site to estimate how the AWAR, WTHR, and site infrastructure contribute to the effects of the Project on caribou.
2. To collect a set of 100 samples of caribou behaviour each year.
3. To use information from the surveys to determine what factors predict caribou behaviour, specifically comparing:
 - Near vs. far;
 - Large groups of caribou vs. small groups;
 - Surveys with and without disturbances;
 - Road open vs. closed; and
 - Upstream vs. downstream side of the road (east or west side, as determined by dominant direction of travel in each season).

3. BACKGROUND

Five caribou sub-populations may interact with the Meadowbank Project Area: Lorillard, Wager Bay, Qamanirjuaq, Beverly, and Ahiak. Primarily, caribou from Lorillard herd interact with the Project, and smaller numbers of caribou from the Ahiak and Wager Bay herds interact with the Project. Collar data indicates that caribou occur mostly in the area in late winter and during fall rut.

3.1 Lorillard Herd

The majority of recorded interactions of collared caribou with the mine site and road have been from Lorillard caribou. The Lorillard caribou herd is a mid-sized caribou herd that numbered 41,000 animals in 2002, with no recent estimates of population size (COSEWIC 2016). Its range occurs entirely in Nunavut, with the core of its range stretching northward from Chesterfield Inlet on the Hudson Bay coast and westward toward Baker Lake.

The herd generally winters on the tundra in northern central mainland Nunavut. Spring migration is westward and north of Chesterfield Inlet, past the community of Baker Lake to a calving ground south of Wager Bay and close to the Hudson Bay coast (Nagy and Campbell 2012). During late April and early May, groups of animals from this herd interact with the community of Baker Lake, Meadowbank Mine, Whale Tail Mine, the AWAR and WTHR (Agnico Eagle 2020).

Following calving, the caribou form into large groups and generally move west and inland, gradually returning west towards their wintering areas by early December (Nagy and Campbell 2012). Throughout this period, caribou may interact with the Project infrastructure.

3.2 Existing Caribou Management Measures

As per the TEMP, during peak migration the road is closed to all but essential mine traffic. During road closures, essential mine traffic typically occurs in the form of scheduled convoys of vehicles travelling tightly in one group to minimize the sensory disturbance to caribou. During non-peak periods, caribou observations near the road trigger speed restrictions that apply to all mine traffic. Road closures are triggered separately for the WTHR and the AWAR. In 2021, the AWAR was closed for 57 days and open with a speed restriction for 39 days. The WTHR was closed for 14 days, and open with a speed restriction for 29 days. Drivers for the mine are also trained to slow when caribou are within sight and follow the mitigation measures outlined in the TEMP.

Caribou surveys were considered an essential activity by the Project, allowing the survey pickup truck to be used on the AWAR and WTHR even when these roads were closed to normal mine traffic.

3.3 Terrestrial Advisory Group

A Terrestrial Advisory Group (TAG) was formed in 2019 as a collaborative forum to discuss Inuit Qaujimajatuqangit (IQ), Traditional Knowledge (TK) and western science applications to mitigation and monitoring programs for the Meadowbank Mine, including on caribou movement in the project area. Members of the group include the Government of Nunavut (GN) and the Kivalliq Inuit Association (KivIA) and the Baker Lake Hunters and Trappers Association (HTO). Following the discussion of the caribou behaviour survey results in 2020, the TAG and particularly KivIA suggested several improvements to the survey protocol and analysis methods. These improvements included adding a variable for road closures and testing whether caribou walking could be considered a response behaviour. Agnico Eagle endeavored to incorporate all of the suggestions of the TAG into the 2021 data collection process and analysis.

4. STUDY AREA

The Meadowbank Gold Mine is located approximately 90 km north of the Hamlet of Baker Lake, and the Whale Tail Pit Project is located approximately 150 km north of the Hamlet. Overall, the Meadowbank Complex, consisting of both mines, processing facility, roads, and associated infrastructure and activities, is approximately 300 km inland from the northwest coast of Hudson Bay and is above the tree line near the Arctic Circle. The local physiography is characterized by numerous lakes and low, rolling hills covered mainly by lichen/rock complexes, and heath tundra.

The study area for behaviour monitoring included the existing footprint for the Meadowbank Gold Mine site, the AWAR, the WTHR, plus a 1 km buffer surrounding these areas (See Figure 1-1). Surveys were conducted on any caribou that could be visually surveyed from Project infrastructure up to a distance of 3 km with the aid of binoculars.

5. METHODS

5.1 Field Surveys

Survey methods followed protocols for monitoring caribou behaviour developed by the Government of Northwest Territories Department of Environment and Natural Resources (GNWT 2017). During 2020, ERM refined these methods for Agnico Eagle's Nunavut mine operations. The updated methods focus on scan samples, *in lieu* of both scan and focal samples. Given time and personnel constraints, this was determined to be a more efficient use of time and produce better quality data that is suitable for statistical analysis. The updated methods also include an initial survey step to randomize which group of caribou to monitor when multiple groups are available. In 2021 these methods were further refined to reflect lessons learned in 2020. The 2021 updates included using a rangefinder to measure distance and recording additional information such as whether the caribou occurred on the east or west side of the road. Detailed survey protocols are attached in Appendix A.

Prior to spring migration, a wildlife biologist from ERM conducted a virtual classroom and practical training program for Agnico Eagle environmental technicians dedicated to the task of behaviour observations.

The overall method for the field surveys was to: identify caribou groups visible from the mine site, AWAR and WTHR; randomly select groups for observation; and record the behaviour of individuals in groups of different sizes, including their responses without any disturbance and in response to mine-related activities and natural factors. Surveys were conducted mainly during the spring migration when the largest number of caribou pass through the Project area, but were also conducted opportunistically during summer and fall migration.

A reconnaissance survey was first conducted to identify where caribou groups were located. Where multiple groups were observed, surveyors chose which group to sample using a random number table, or specifically chose groups to fill data gaps. Field methods included the recording of site information at the location of each survey, including GPS coordinates, weather conditions, road structure, and location of the caribou group in relation to the surveyors and the road. Individuals in the observed-group were categorized when the survey started and every three minutes (referred to here as a "time interval") until 30 minutes had elapsed.

Behaviour categories and their definitions were standardized following GNWT (2017) classifications. The behaviour categories were: feeding, lying down, standing, alert, walking, and trotting or running.

At each three-minute interval, surveyors recorded the numbers of individuals in the group exhibiting each behaviour at that time. If the group was too large to be counted in each interval (>100 individuals), an identifiable subset of the group was surveyed during each interval and the total group size was recorded on the datasheet. In the case that a disturbance event occurred during the survey the time and type of disturbance was recorded. A **disturbance** is defined as any human-caused loud noise, low-flying aircraft, or vehicle travelling on the road. Of the disturbances recorded in 2020 and 2021, 97% were from road related disturbances (vehicles) and 3% were from blasts or helicopters. In the analysis all disturbances are treated equally.

Alert behaviour and trotting or running were considered disturbance "**response behaviours**" and were grouped together in the subsequent data analysis. In this report, alert and running behaviours are referred to collectively as response behaviours, but it is important to note that this is irrespective of whether or not there were disturbances recorded. Caribou may exhibit these behaviours without a disturbance occurring. Walking was also assessed as a response behaviour in some analyses, which are specifically noted in the results.

Following recommendations from the TAG in 2021, an additional set of longer surveys was completed to specifically look at the behavioural response to convoys of vehicles. These surveys were 90 minutes each, consisting of a “before convoy”, “during convoy” and “after convoy” survey. Observers sought out caribou that were likely to remain within view for 90 minutes, such as caribou that were feeding or laying down. Nine surveys were completed using this extended methodology. These are explored visually in the results, but were not analysed in a separate statistical analysis due to the small sample size.

5.2 Data Analysis

The objective of the data analysis was to quantify trends in the survey data, and determine whether factors such as distance to Project infrastructure (road), group size, or the disturbances could be used to explain caribou behavior. The primary hypothesis was that caribou closer to the road would demonstrate a stronger response to disturbances. An initial exploratory analysis was conducted to visualize the data and determine the appropriate method for analyzing the data.

A regression analysis was conducted to test whether the data from these surveys could be analyzed statistically. To increase the power to detect changes in caribou behaviour, the behaviour categories were grouped for analysis into “response” behaviours (alert and running) and non-response behaviours (feeding, lying down, standing, and walking).

Following the 2020 analysis, there was a suggestion from the TAG to explore whether the proportion of walking caribou changed as a response to disturbance. This was done to see if walking would be better categorized as a response behaviour or a non-response behaviour. For the analysis, walking data was still kept separate from running or alert behaviours (the previous response behaviours), because the proportion of caribou walking was substantially higher at any given time than the proportion exhibiting alert or running behaviour. Grouping the three “response” behaviours together would risk washing out the potentially higher stress behaviours of alert and running.

Generalized linear mixed-effects models (GLMMs) were used to assess the differences in the proportion of response behaviours in surveyed animals as a function of various controlling variables, including the occurrence of disturbances. This regression framework provides a means to control for habitat, environmental variables, repeated measurements, and spatial correlation.

Statistical analyses were conducted using the data from each three-minute time interval in each survey. To reiterate, each survey consisted of 11 observations: Minute zero plus 10 three-minute time intervals, totalling one 30-minute survey. Three dependent variables were tested:

1. The first dependent variable tested was the proportion of response behaviours in each time interval, modelled using a binomial distribution.
2. The second dependent variable tested was the proportion of walking behaviour in each time interval, modelled using a binomial distribution.
3. A third dependent variable was developed to track the number of minutes it took caribou to return to background behavior levels every time there was a disturbance. In order for a response to be included, the proportion of alert or running caribou after a disturbance had to be 40% greater than in the interval before disturbance. The response was considered “over” when the proportion of alert or running caribou returned to with the level observed in the interval before the disturbance ($\pm 5\%$). This variable, called “duration of response”, was assessed for each survey and modelled with a normal distribution.

The three dependent variables were modelled against a suite of potentially important variables to determine if there was any statistical relationship with response behaviour. The variables included in this analysis were group size, distance to road, temperature, wind speed, season and side of the road (upstream/downstream), the roads status (closed or open), and a binary variable identifying whether or

not a disturbance occurred in the survey. Season and side of the road were included as an interaction term, because direction of travel is seasonally dependent. This means that season and side of the road are included in the model together as an interaction *and* individually as fixed effects. The interaction term makes it possible to identify the “upstream” and “downstream” side of the road, based on the season. A random effect was included for survey ID, because the three-minute intervals within each 30-minute survey are interrelated.

Because the proportion of responding caribou in a given interval is potentially linked to the conditions in the intervals before, two additional binary variables were added identifying whether a disturbance occurred in the interval prior, and whether a disturbance occurred two intervals prior. This accommodation for a six minute “lag” was sufficient for the majority of disturbance events, which typically did not result in a response longer than three minutes. Lastly, the survey ID was added as a random effect to account for general behavioural differences between groups of caribou surveyed.

For each dependent variable, GLMMs were constructed and tested for model fit, as evidenced by the Akaike Information Criterion (AIC). AIC is a number that is helpful for comparing models as it includes measures of both how well the model fits the data and how complex the model is (simpler is usually better). The top models were identified as having a low AIC and were within a 2 unit difference in AIC ($\Delta AIC \leq 2$) of the top ranked model (i.e., the model with the lowest AIC; Burnham & Anderson 2004). This is the industry standard for identifying models that are essentially ‘equally good’ at explaining the data. Models with a difference in AIC (ΔAIC) of 2 to 4 from the top model are generally considered to have ‘limited support’.

6. RESULTS AND DISCUSSION

6.1 Caribou Distribution relative to the Project

During spring migration in 2020 and 2021, caribou GPS collar locations were provided to Agnico Eagle. These data indicated when caribou were approaching the Project site. Viewsheds or road surveys were conducted as required by Agnico Eagle environment technicians in order to trigger management actions. These data informed the decision to begin dedicated behaviour surveys for caribou as they approached the site. Through the summer, surveys were conducted opportunistically as caribou were observed. A final set of dedicated surveys was conducted in the fall during peak fall migration.

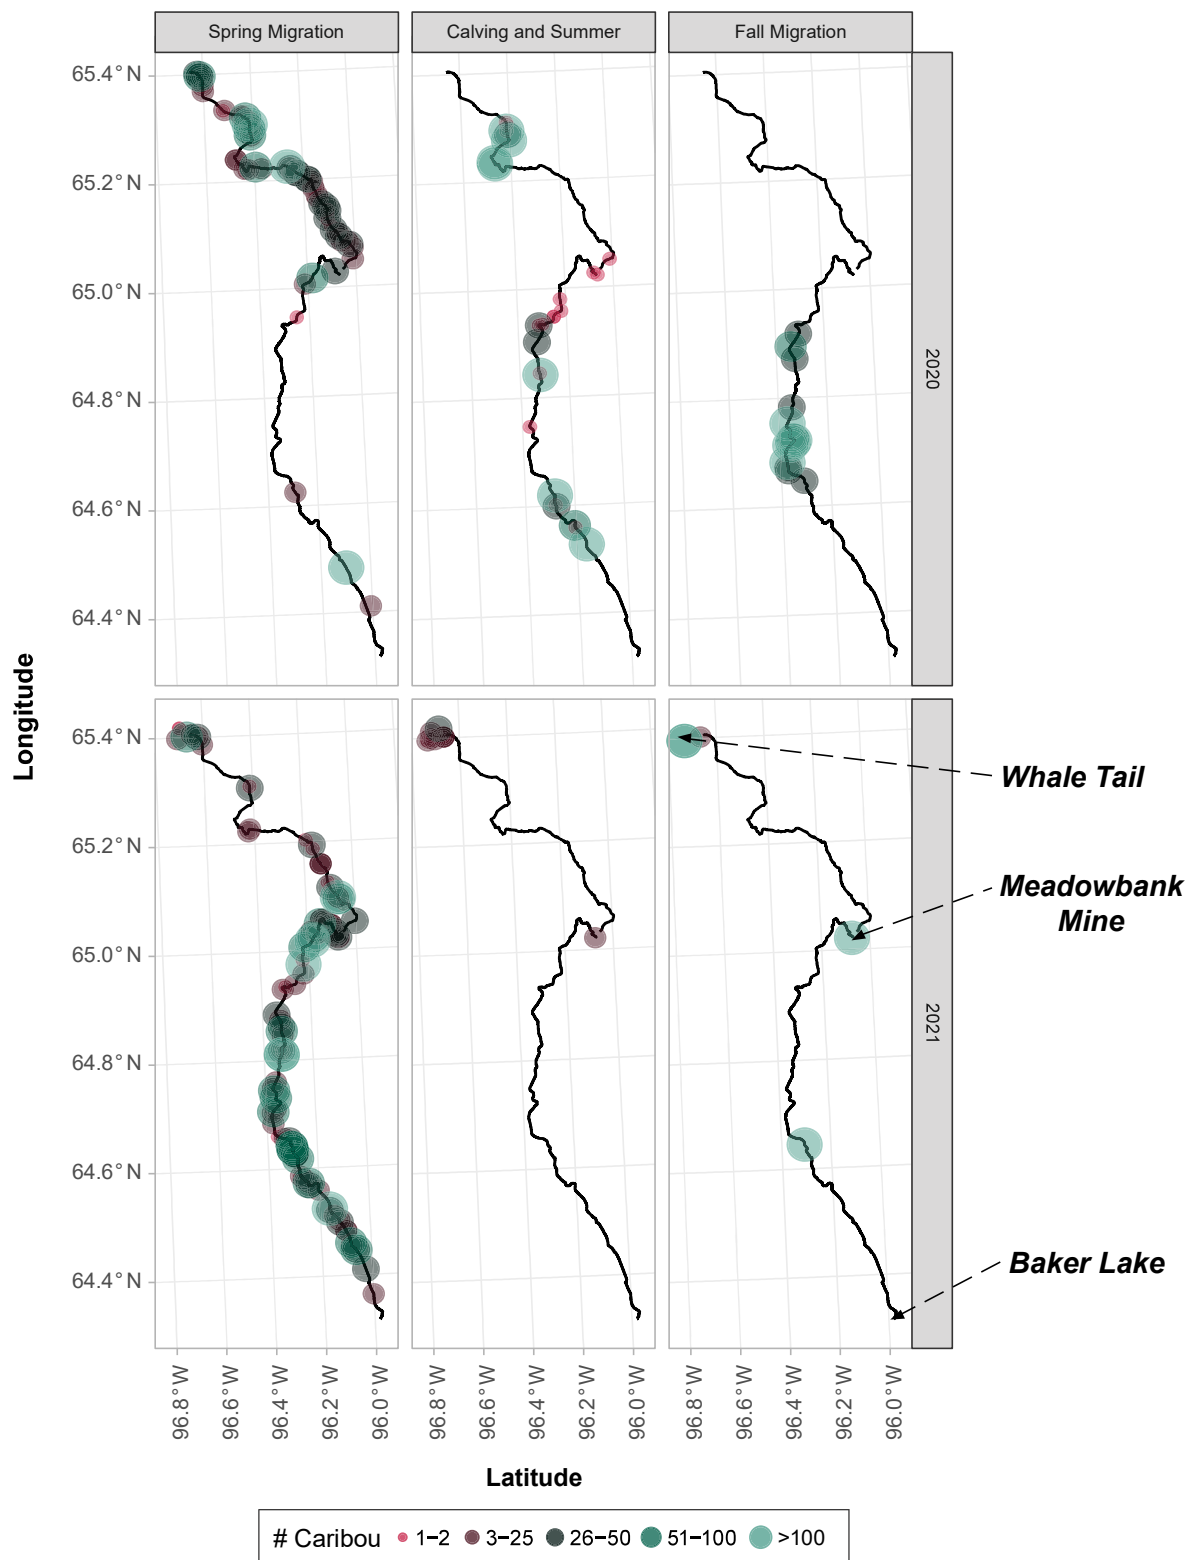

Survey locations by season are presented in Figure 6.1-1. During spring migration (March to May), calving/summer (June to August) and fall migration (September to December), scattered groups of caribou from the Lorillard herd were observed passing through or near the study area, with the highest numbers of caribou observed in May. During spring migration in 2020, the majority of surveys were conducted on the WTHR, as this was where the caribou were observed. In contrast, the 2021 spring season saw more caribou along the AWAR. During summer and during fall migration in 2020, caribou were observed more frequently in the southern portion of the study area along the AWAR, but these trends were not clearly visible in 2021, perhaps due to the smaller sample size.

6.2 Caribou Behaviour Field Surveys

In total, 134 behaviour surveys were conducted in 2021 when groups of caribou were near the Project (Table 6.2-1), including 114 surveys in spring migration, 15 surveys in calving and summer, and five surveys in fall migration. This is compared to the 116 total surveys completed in 2020, including 58 surveys in spring migration, 18 surveys in calving and summer, and 13 surveys in fall migration. However, in 2021 the survey effort was concentrated during spring migration, and fewer surveys were completed in summer and fall compared to 2020. Surveys were conducted opportunistically whenever caribou were encountered during reconnaissance drives, primarily along the AWAR and WTHR.

Overall, the survey methodology worked well for the Project location and circumstances, and the survey results were generally consistent between 2020 and 2021. All reported results use the combined data from 2020 and 2021, unless otherwise stated. General observations on survey methodology and results included:

- Surveys were well distributed across a range of group sizes (Table 6.2-1). Surveyors reported that the addition of a reconnaissance survey and random selection of survey group assisted with a relatively even distribution of survey intensity across group sizes.
- Of the 250 surveys, more than half recorded at least one disturbance during the survey (Table 6.2-1). Most of these disturbances were haul trucks and light trucks travelling between Whale Tail and Meadowbank. On the AWAR, the disturbances were sometimes ATVs travelling north from Baker Lake. Mine traffic was suspended during periods when groups of caribou were near the road.
- In total, 60% of disturbances were from heavy vehicles (including haul trucks, tractor trailers, fuel trucks, and graders), 33% were from light trucks, 5% were from ATVs, and 2% were from helicopters.
- The methodology allowed for the estimation of baseline behaviour, response to disturbance, and return to baseline behaviour. Few, if any, surveys ended before caribou returned to baseline behaviour. Thus, 30 minutes appears to be an appropriate survey length.
- One source of uncertainty was consistently estimating distance. Hence, the average distance of each group of caribou was categorized into blocks of 0-50 m, 50-100 m, etc. Though distance was estimated with a rangefinder in 2021, the data were still binned into distance intervals to allow the two years of data to be analysed together.

Note: Colour and size indicate group size, and the location of the All-Weather Access Road and Haul Road is indicated by the black line.

Figure 6.1-1: Locations of Behaviour Surveys by Season

- The goal of 100 surveys suggested by the GNWT methods was easily achieved at Meadowbank. Between spring migration, summer, and fall migration, caribou may interact with Project infrastructure for long periods across four months. Therefore, 100 surveys is likely an achievable goal for future years of behaviour monitoring at Meadowbank.
- In 2020, only 16% of surveys were conducted on caribou within 300 m from the road at the start of the survey. In 2021, an effort was made to increase the number of surveys on caribou within 300 m of the road, and this resulted in an increase to 43% of surveys.
- Most caribou behaviours were calm, generally foraging, and not moving quickly (non-response). The one exception was smaller groups who moved more than larger groups – more walking and trotting. As a consequence, caribou were observed crossing the road in only 4% of surveys in 2020 and in 4% of surveys in 2021, primarily in small groups of less than 25 individuals. In total, seven crossings occurred during road closures, one during speed restrictions, and three when the road was open.
- During spring migration when caribou move east towards their calving grounds, 79% of caribou were observed on the west (upstream) side of the Project infrastructure (Table 6.2-2). This was consistent across both years of surveying. During summer and fall migration, caribou move west towards their overwintering grounds. In 2020, 68% of caribou were observed on the east (upstream) side of the Project infrastructure, but in 2021, the opposite trend was true (Table 6.2-2). This inconsistency may be a reflection of the smaller sample size in the later seasons in 2021.

Table 6.2-1: Meadowbank Complex Caribou Behaviour Surveys Data Summary, 2020 to 2021

Caribou Group Size	Total Surveys (Both Years)	Total Surveys 2020	Surveys with Disturbances 2020	Surveys with Observed Road Crossings 2020	Total Surveys 2021	Surveys with Disturbances 2021	Surveys with Observed Road Crossings 2021
1-2	51	28	15	1	23	15	0
3-25	98	35	22	1	63	35	2
26-50	49	28	13	2	21	9	0
51-100	26	9	5	0	17	9	0
>100	26	16	13	1	10	6	4
Total	250	116	68	5	134	74	6

Table 6.2-2: Summary of Spatial Distribution of Surveys

Season	Surveys of Caribou on East Side of the Project Infrastructure 2020	Surveys of Caribou on West Side of the Project Infrastructure 2020	Surveys of Caribou on East Side of the Project Infrastructure 2021	Surveys of Caribou on West Side of the Project Infrastructure 2021
Spring Migration	12	46	23	89
Calving/Summer	11	7	3	12
Fall Migration	10	3	1	4
Total	33	56	27	105

Note:

Side of the road data was not recorded in 27 surveys in 2020. It was recorded in all surveys in 2021.

The “upstream” side of the road is based on the dominant direction of travel and is indicated with grey shading.

6.3 Exploratory Analysis Results

The exploratory analysis was conducted to determine if there were any trends or interactions in the following variables: road crossing group size, distance to infrastructure (AWAR, WTHR and mine site), weather and timing, road closure status, side of the road (east or west), number of disturbances, and response time following disturbances. Finally, the results of the nine convoy surveys conducted in 2021 are explored in Section 6.3.8.

6.3.1 Comparing Road Crossings with Group Size and Distance to Infrastructure

6.3.1.1 Road Crossing

Plotting the data did not show a clear relationship between caribou group size and the observation of road crossings. Although in 2020, four of the five observed road crossing events occurred in groups smaller than 25 individuals, the trend was less apparent in 2021 when observations of road crossings included both large and small groups. There was also no clear relationship between caribou distance from road and the observation of road crossings, meaning that caribou located closer to the road were not more likely to cross the road than caribou positioned further away (Figure 6.3-1a).

6.3.1.2 Group Size and Distance to Infrastructure

Plotting the caribou group size against the distance of caribou groups to the road at the start of the survey revealed that small groups (less than 50 individuals) were observed at all distances within the study area (Figure 6.3-1a). Note that distance to the road and distance to the observer/surveyor are considered equivalent in this analysis.

In 2021, particular effort was taken to increase the sample size of caribou (and specifically large groups of caribou) within 300 m of the road at the start of the survey. In spite of this there is still a slight trend for larger groups to be observed further from the road at the start of the survey (Figure 6.3-1b). Only two groups larger than 100 individuals were recorded within 100 m of the road at the start of the survey, both in 2021.

This may be indicative of a trend that caribou tend to avoid areas within 100 to 300 m of the road, or may be a by-product of observability bias, where smaller groups are more difficult to spot at distances greater than 300 m away from the road. Regardless of the mechanism, these trends highlight a potential source of error and were considered in the statistical analyses so that the results were not biased (see Section 6.4.1).

6.3.2 Comparing Behaviour Type with Group Size and Distance to Infrastructure

Average proportions of each behaviour type by group size and by distance to road are presented in Figure 6.3-2. When analyzed by group size, the results suggest that the average proportion of the response behaviours of “Alert” and “Trotting” remain stable as group size increases. The largest proportion of alert or trotting behaviours was observed in groups of one to two individuals. No group size had more than 10% alert or trotting, when averaged across observations with and without disturbances (Figure 6.3-2a).

When analyzed by distance to road, the results suggest that the proportion of response behaviours is relatively stable for groups within 1,000 m of the road and lower in groups further than 1,000 m from the road, but the difference is very small – at most one or two percent lower (Figure 6.3-2b). As with group size, no distance category had surveys with more than 10% of caribou with alert or trotting behaviour.

Overall, no clear differences in behaviour can visually distinguished among group sizes or distances to the road. These relationships are examined in greater detail in the statistical analysis.

Figure 6.3-1: Caribou Group Size Versus Distance From the Surveyors to the Caribou at the Start of the Survey

Figure 6.3-2: Average Proportion of Each Behaviour Type Observed Among at the Start of the Survey.

6.3.3 Behaviour Type and Environmental/Temporal Variables

Figure 6.3-3 shows the relationship between 1) the proportion of response behaviours and 2) environmental and temporal variables: temperature, wind speed, and date. This comparison was included to exclude the possibility that environmental factors such as heat or high winds were influencing caribou behaviour during the survey. No trend is visible in the data and trend lines fit to the weather data are nearly flat with wide confidence intervals, suggesting that the weather conditions observed during the surveys do not have a substantial effect on behaviour. It should be noted that surveyors typically did not go out in extreme weather events and therefore variability in weather conditions was low. Date was also not associated with caribou behaviour.

6.3.4 Road Closure Status

An additional comparison was added in 2021 to explore the effect of the road closure status on average caribou behaviour. During caribou active months, the road may be open, closed, or open with speed restrictions. During peak caribou migration the road is closed, with some allowances for essential traffic in convoys.

Surveyors were out collecting data when the road was open and when it was closed, as caribou surveys were considered an essential activity. As a result, there are relatively even numbers of surveys from when the road was open vs. when it was closed (Figure 6.3-4). Although it was expected that the level of response behaviours would be higher on average when the road was open due to an increase in traffic, this difference is not visually apparent. The level of response behaviour (averaged across all observations with and without disturbances) is low (<10%) both when the road is closed and when the road is open.

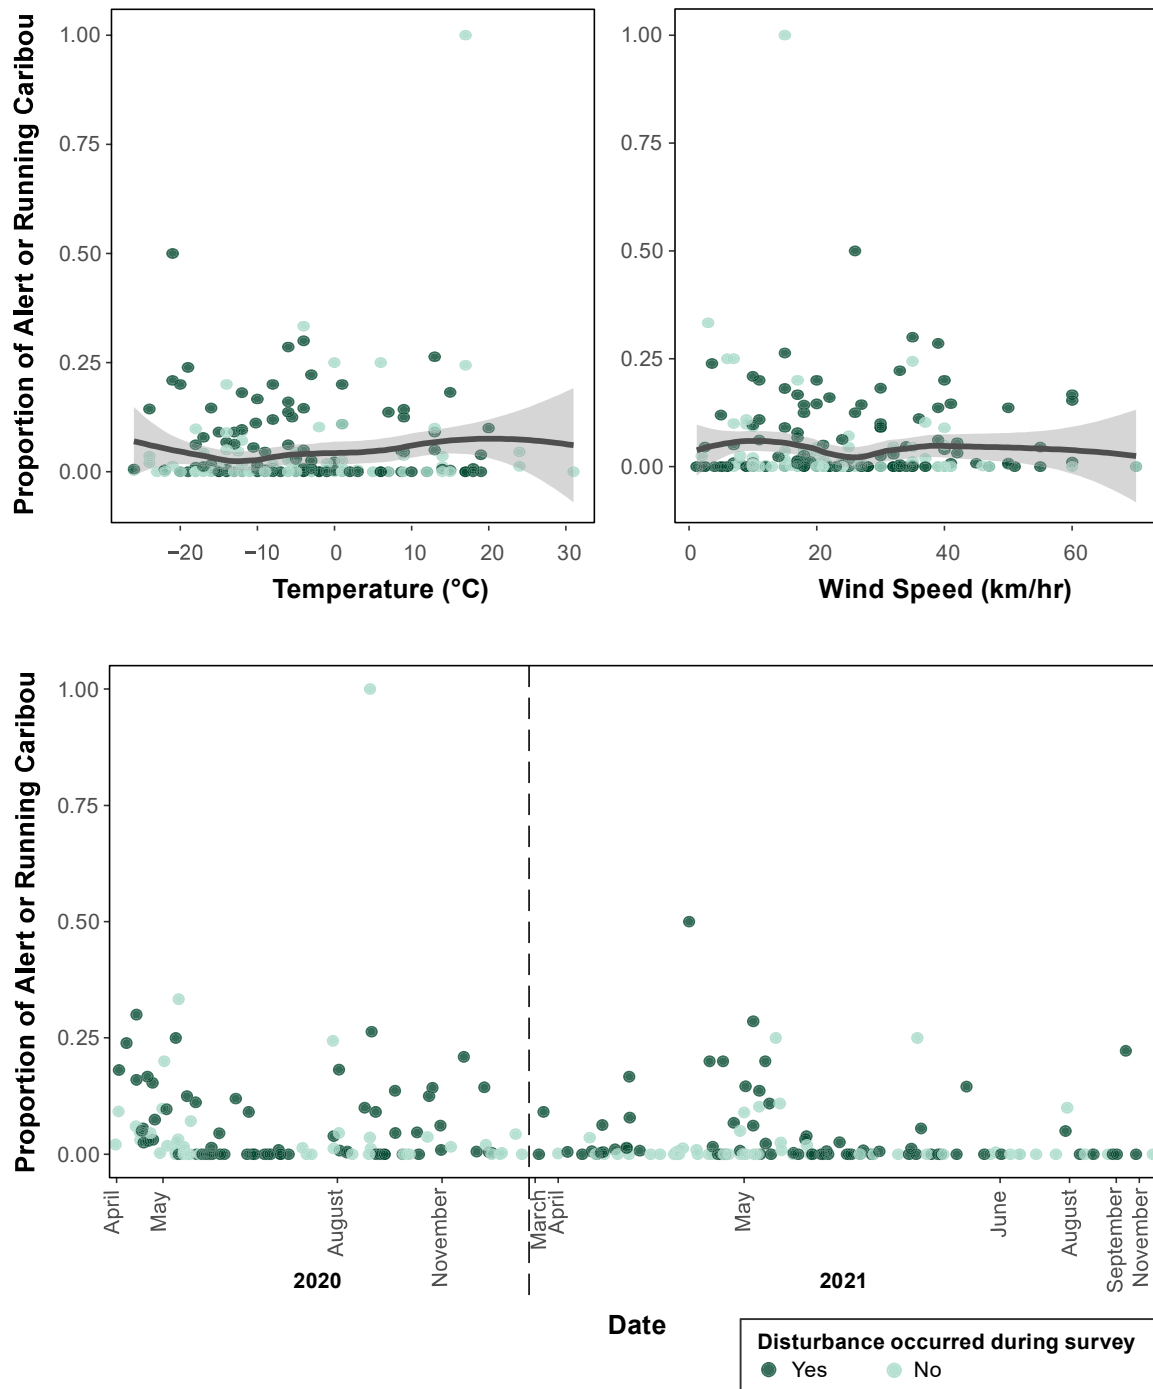

It should be noted that convoy surveys were included in the summary figure, and these always occurred during road closures. However, this accounts for only 8% of surveys during road closures, so cannot entirely explain the differences observed in Figure 6.3-4. This relationship is further explored in the statistical analysis.

6.3.5 Season and Side of the Road (Upstream/Downstream)

The movement pattern for caribou in the Project area is variable based on the season. During spring migration, the dominant direction of travel is west to east, whereas in summer and during fall migration it is east to west. It was hypothesized that behaviour may vary depending on whether the caribou had crossed the road already ("downstream") or whether they were anticipating doing so ("upstream").

One hypothesis is that caribou are hesitating to cross the road but that once they cross the road, they move away quickly. If this were the case, the prediction would be that groups of caribou would be observed close to the road on the upstream side with fewer groups or groups further away on the downstream side. This predicted distribution was not observed. Instead, groups of caribou were observed near the road on both sides of the road. Figure 6.3-5 compares the distance to the road at the start of the survey with the location relative to the road (east or west). In spring migration, a greater number of surveys were recorded on caribou on the west side of the road, which is upstream for that season. This may be an indication that caribou tend to gather before crossing the road.

While differences in response behaviour (running/alert) do not appear to vary with the side of the road the observations are from, one trend that does stand out is that there appears to be a higher proportion of walking behaviour on the upstream side of the road. This is explored further in the statistical analysis.

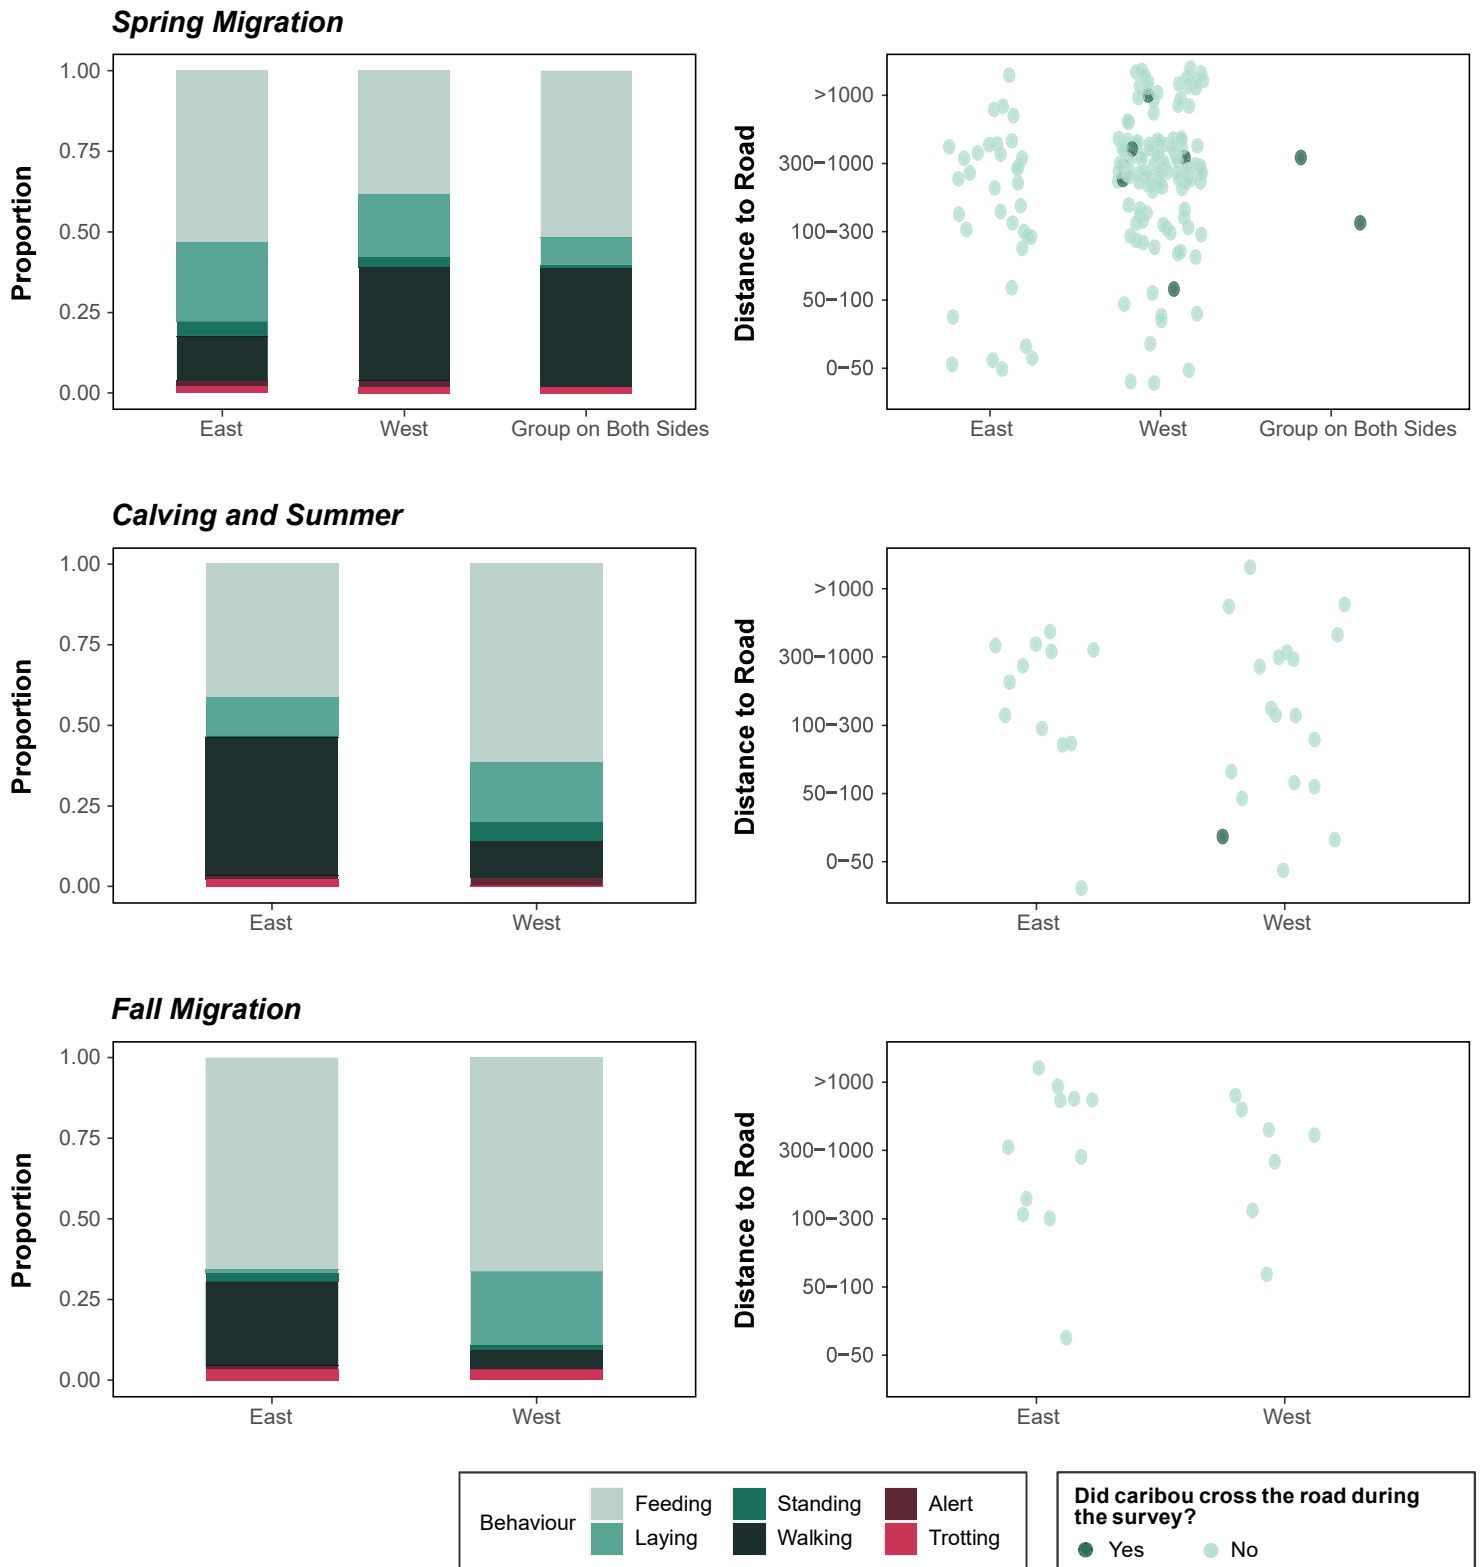

Notes: Colour indicates whether or not a disturbance occurred during the survey.
In the top two panels, an exploratory loess smooth fit is shown in grey with 95% confidence intervals.

Note: Caribou generally travel West to East in Spring and East to West in Summer and Fall

Figure 6.3-5: Comparison of Caribou Behaviour on East and West Side of the Road By Season (Upstream/Downstream)

6.3.6 Number of Disturbances

When duration of response (i.e., time taken for caribou to return to a baseline condition following a disturbance) is compared with the proportion of response behaviours, it appears that surveys with a higher proportion of caribou responding to the disturbance tend to take longer to recover to a baseline condition (Figure 6.3-6 panel a). Interestingly, it appears that surveys with multiple disturbances don't consistently produce a larger response or a longer one. Although the long-lasting full-group responses are in surveys with multiple disturbances, there are surveys with multiple disturbances that don't have large reactions or longer-lasting response durations.

Figure 6.3-6 (panel b) shows a density plot for the proportion of response behaviours in three subsets of surveys; those with no disturbances, those with one disturbance, and those with multiple disturbances. The results suggest a slightly higher proportion of alert or running caribou in surveys when one or more disturbances occurred. Surveys with multiple disturbances do not appear to have a greater overall response than surveys with one disturbance. It should be noted that this figure is an average proportion of response behaviours across the entire 30-minute survey, so in some instances the proportion of response behaviours may have been obscured by the large number of intervals with no response behaviour.

6.3.7 Response to Disturbances

Summarizing data over the entire 30-minute survey is useful for broad comparisons, but has the disadvantage that response behaviour can be washed out in a relatively uneventful survey. To examine the response to disturbances within a survey, the proportion of response behaviours was plotted by three-minute interval for each survey, as shown for a subset of surveys in Figure 6.3-7. See Appendix C for plots of all surveys. In Figure 6.3-7, the response behaviours of "alert" and "trotting or running" are combined to create the total proportion of responding caribou in any given time interval, and plotted over time within the 30-minute survey. Disturbances are denoted with a vertical bar. A spike in response behaviours in the interval during a disturbance or immediately following a disturbance suggests that the caribou are responding to the disturbance.

The results show that in the absence of disturbances, an average of 0-10% of caribou typically exhibit response behaviours at any given time. Figure 6.3-7 and Appendix C suggest that following many of the disturbance events, there was commonly a spike in the proportion of response behaviours to 60-90% of caribou in the group. Following a disturbance event, there was commonly a spike in the proportion of caribou with response behaviours increasing from 0-10% up to 60-90% of the group. The proportion of caribou with response behaviours returned to a pre-disturbance levels quickly, often within two intervals (6 minutes). For example, when a truck passed, most caribou would look up (which is classified as a response behaviour) and then return to feeding or laying down (a pre-disturbance behaviour).

There was some variability in the proportion of response behaviours. During some surveys, there was a spike in response behaviours when no vehicle or other obvious disturbance was observed. Or, as in the case of survey #1, background levels of response behaviours are high leading up to a disturbance. In the future, these surveys should be flagged for a manual assessment of response duration. In some surveys a vehicle passed by (a disturbance), but there was no increase in response behaviours observed in the caribou group on the subsequent time period.

6.3.8 Convoy Surveys

The results of the nine 90-minute convoy surveys are shown in Figure 6.3-8. Surveyors were not always able to keep track of a group of caribou for the entire 90 minute duration, so the start and end time of the survey is denoted by vertical grey bars. The time interval in which the convoy passed closest to the caribou group is denoted by a vertical red bar. Missing data within the survey indicates that the caribou were out of sight for those time intervals.

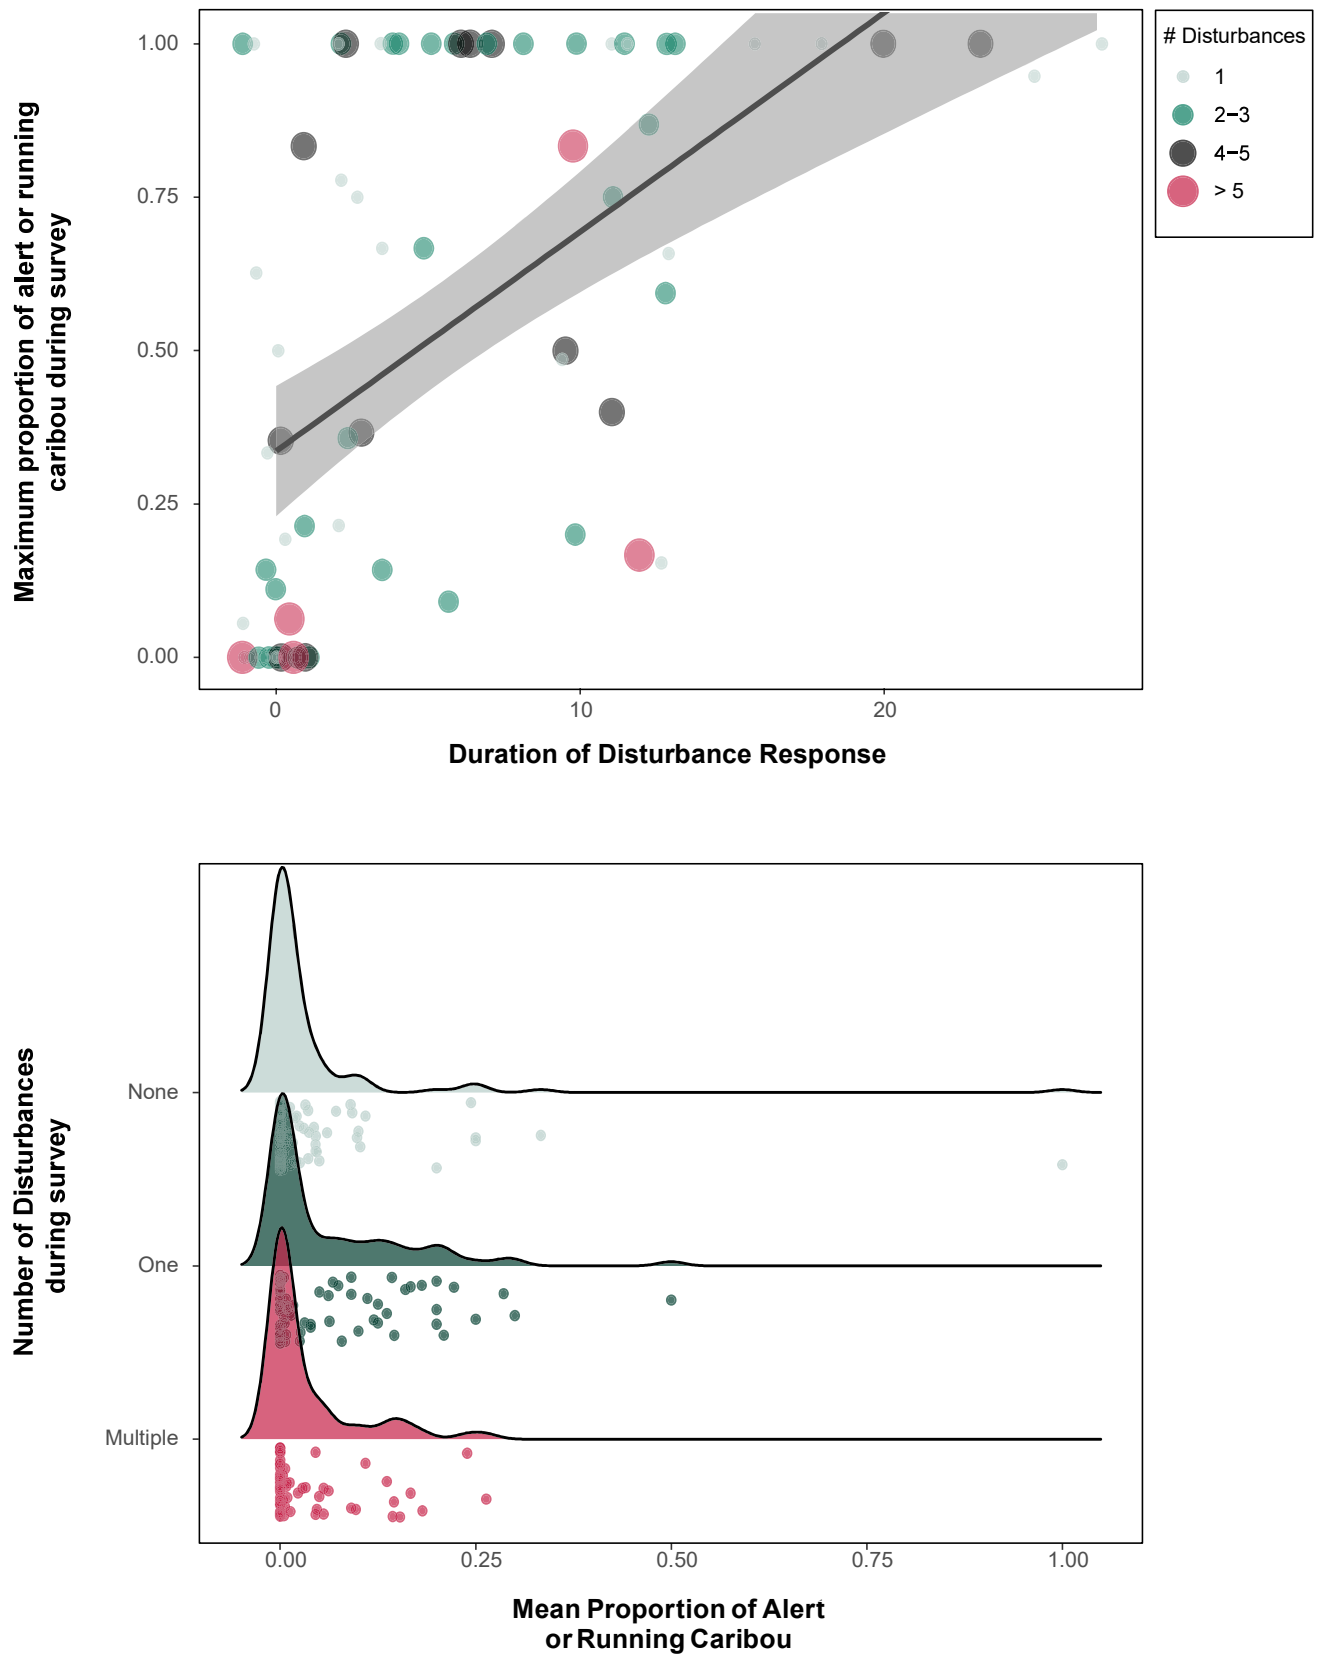

Figure 6.3-6: Comparison of Response Behaviours by Number of Disturbances

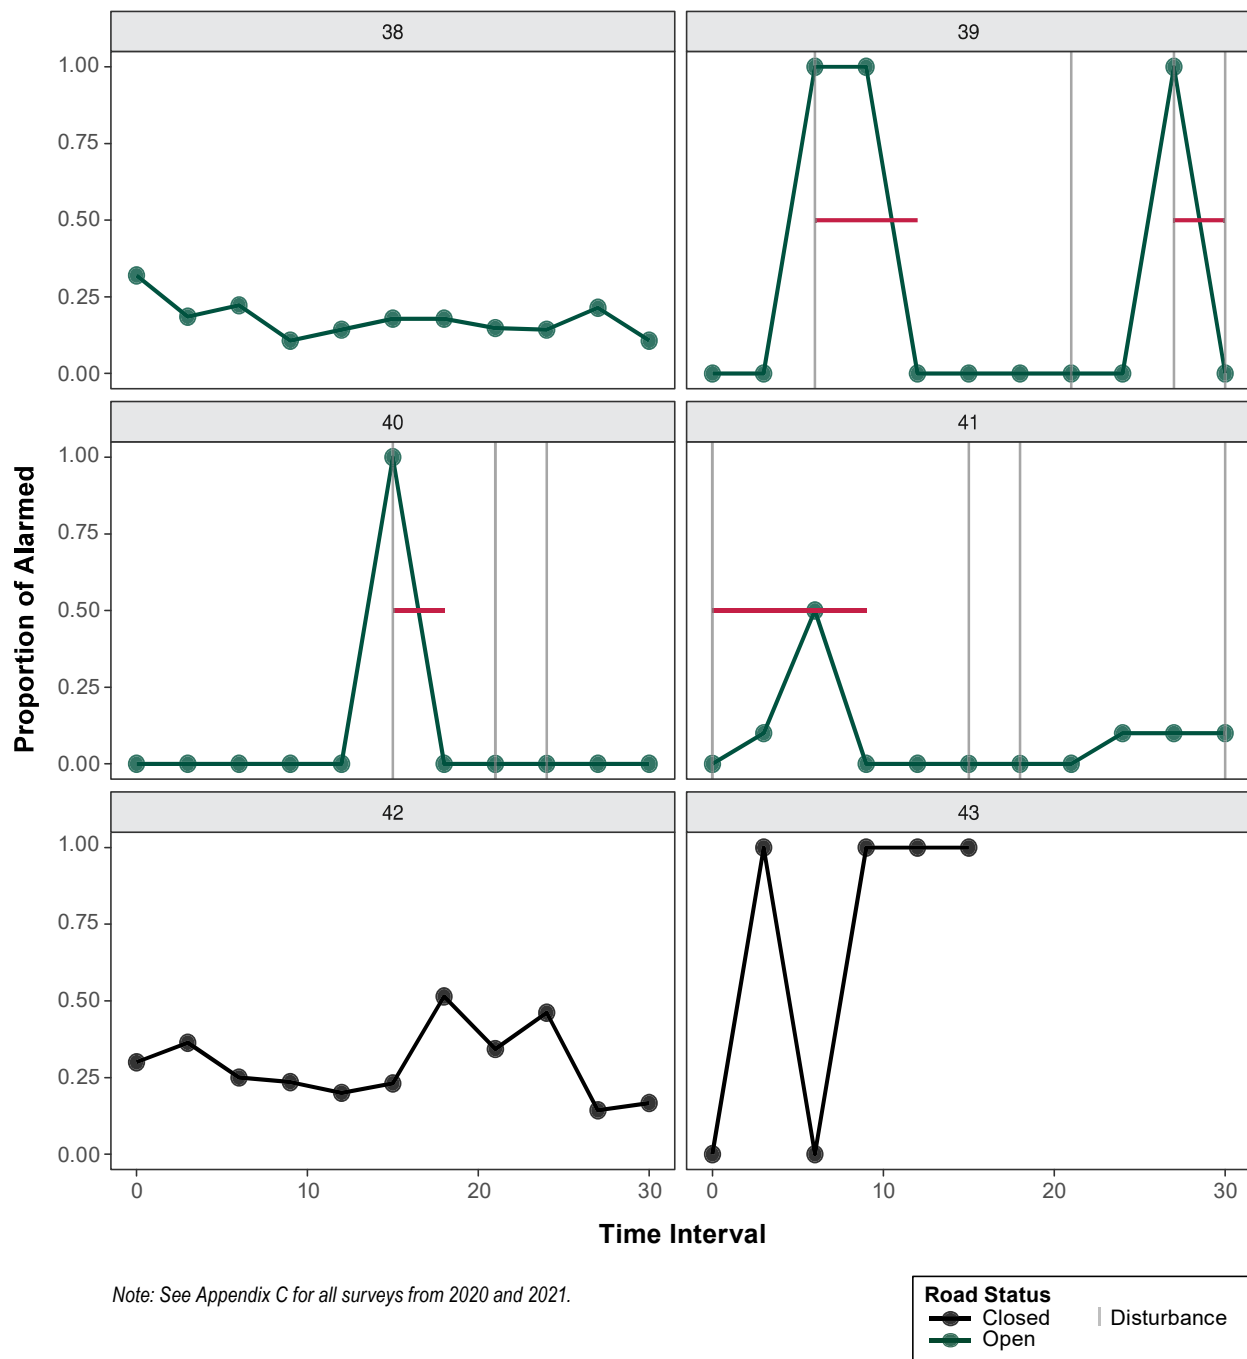

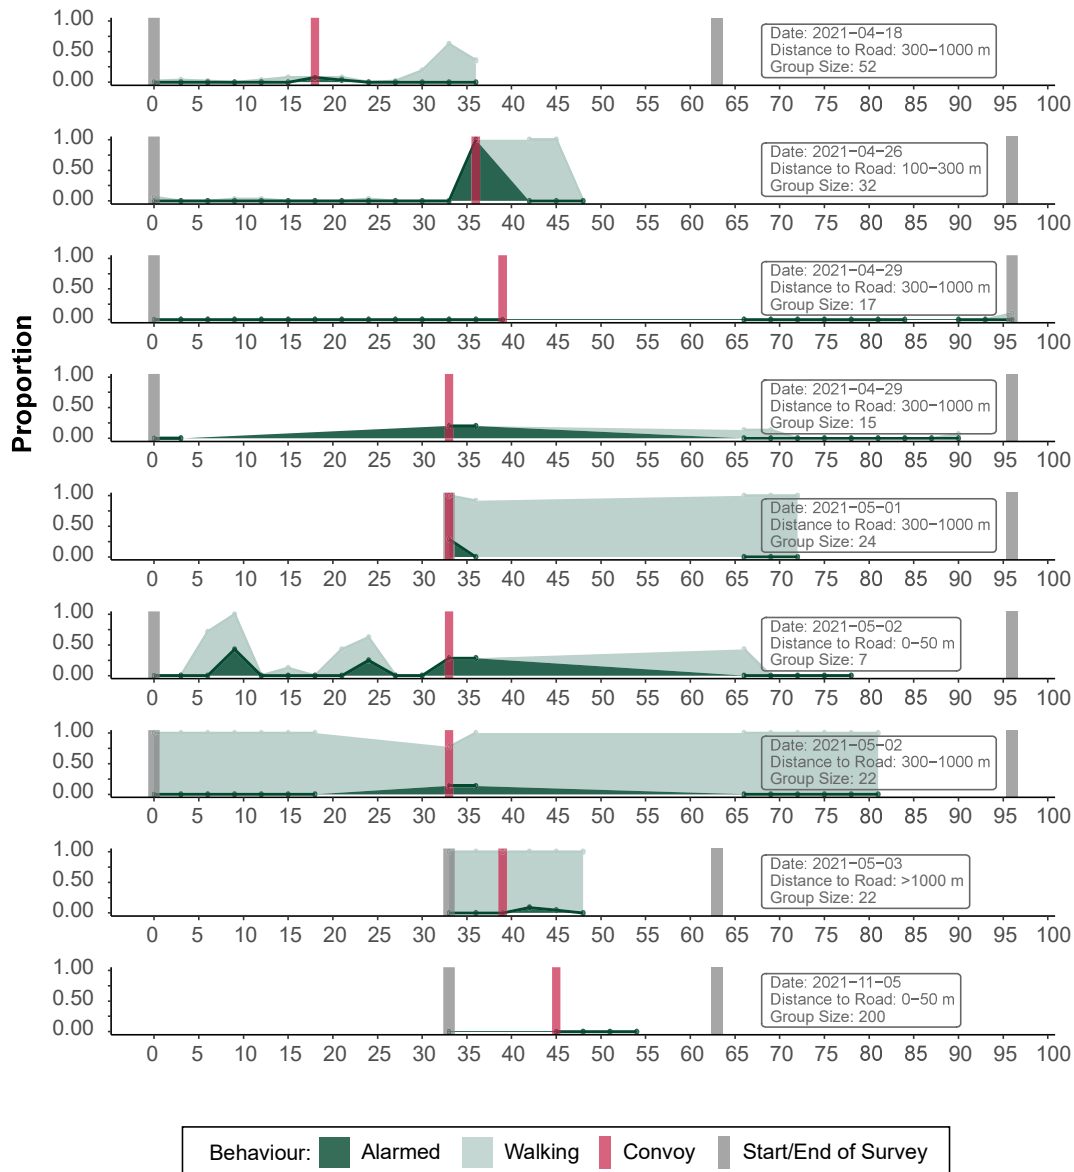

Figure 6.3-7: Proportion of Alert or Running Caribou During Each Survey - Example Subset

Time intervals without data indicate that the caribou group was out of sight from the surveyors.

Figure 6.3-8: Proportion of Alert, Running and Walking Caribou During 90-Minute Convoy Surveys

The results indicate that the passing convoy typically resulted in a spike of response behaviours, consistent with the results seen for other vehicle types (see Figure 6.3-7). The proportion of responding caribou appeared to return to a baseline amount within 15 minutes, but the result was variable. This may indicate a slightly longer duration of response than with other vehicle types, but more surveys would be required to form a conclusion.

To explore the possibility that walking is a response behaviour, the proportion of walking behaviours is plotted in addition to the original response behaviours. The proportion of walking caribou appeared to increase following the convoy in some cases, but in cases where the caribou were walking before the disturbance occurred, the proportion of walking caribou *decreased* following the convoy. This may indicate that walking is more variable as a response behaviour than alert or trotting behaviour.

6.4 Statistical Analysis Results

6.4.1 Model Formulation

As distance to road and caribou group size were identified as being potentially correlated during the exploratory analysis, a Chi-square test was conducted between the two variables to determine if they were too closely related to be included in a model together. A Chi-square (χ^2) statistic is a test that measures how a model compares to actual observed data, and can be used to test for the correlation between two categorical variables. The resulting Chi-square statistic was not significant ($p=0.237$), indicating that group size was not statistically associated with distance from the road. As a result it was determined to be acceptable to model both variables together.

Initial model results suggested that group size was not a good predictor for response behaviour, regardless of how models were parameterized. In addition, a potential issue was identified that smaller groups of caribou would naturally have greater variability in values, and this could bias the results. For example, a group of two caribou is far more likely to have 100% of caribou responding to a disturbance than a group of 50 caribou. As a result, it was deemed necessary to include group size in models as an “offset”, which is a statistical term for a variable that is used to denote the exposure period. It is typically used for situations where some surveys are longer than others, but in this case can be applied to the problem of unequal sample size. All final models presented here use an offset for group size.

All models included survey ID as a random effect because the time intervals within each survey are not independent from each other. The final models had many parameters and with the addition of the random effect it was difficult to attain model convergence. As a result, model variables that had little or no explanatory power and were not variables of interest (such as wind speed) were dropped from the final model sets. An optimizer was also added to the model to run many iterations of the model, increasing the likelihood of convergence.

Three response (dependent) variables were tested in three separate model sets: proportion of response behaviour (alert or running), proportion of walking behaviour, and duration of response following a disturbance.

The estimates and significance levels for the best-fitting model that used response behaviour as the dependent variable are presented in Table 6.4-1, for the best-fitting model that used walking behaviour as the dependent variable in Table 6.4-2, and for the best-fitting model that used duration of response as the response variable in Table 6.4-3.

Table 6.4-1: Summary of Model Coefficients and Significance Levels for Response Behaviour Model

Variable	Estimate	Standard Error	P-value	Significant
(Intercept)	-9.25	0.93	0.000	***
Distance from caribou to observer location (300-1000 m)	0.38	0.86	0.656	
Distance from caribou to observer location (100-300 m)	-0.86	1.39	0.538	
Distance from caribou to observer location (50-100 m)	2.85	1.18	0.016	*
Distance from caribou to observer location (0-50 m)	1.60	1.25	0.200	
Disturbance during interval (Yes)	1.83	0.53	0.001	***
Disturbance one interval prior (Yes)	0.90	0.59	0.127	
Disturbance two intervals prior (Yes)	-0.80	0.93	0.390	
Temperature (°C)	0.59	0.30	0.054	.
Road Status (Closed)	0.05	0.64	0.944	

Note: Statistically significant p-values <0.05 are indicated with a single asterisk. Highly significant values ($p < 0.001$) are indicated with three asterisks. Near significant values ($0.09 > p > 0.05$) are indicated with a dot.

Table 6.4-2: Summary of Model Coefficients and Significance Levels for Walking Model

Variable	Estimate	Standard Error	P-value	Significant
(Intercept)	-3.76	1.00	0.000	***
Distance from caribou to observer location (300-1000 m)	-0.32	0.66	0.623	
Distance from caribou to observer location (100-300 m)	-1.54	0.84	0.067	.
Distance from caribou to observer location (50-100 m)	-0.36	1.14	0.755

Side of Road (West)	0.39	0.80	0.623	
Interaction (Calving and Summer * West)	-1.98	1.53	0.195	
Interaction (Fall Migration * West)	-4.86	2.24	0.031	*

Note: Statistically significant p-values <0.05 are indicated with a single asterisk. Highly significant values ($p < 0.001$) are indicated with three asterisks. Near significant values ($0.09 > p > 0.05$) are indicated with a dot.

Table 6.4-3: Summary of Model Coefficients and Significance Levels for Duration of Response Model

Variable	Estimate	Standard Error	P-value	Significant
(Intercept)	4.41	3.01	0.148	
Distance from caribou to observer location (300-1000 m)	2.93	5.22	0.576	
Distance from caribou to observer location (100-300 m)	2.19	2.71	0.423	
Distance from caribou to observer location (50-100 m)	3.34	2.37	0.163	
Distance from caribou to observer location (0-50 m)	3.12	2.66	0.244	
Caribou group size	0.03	0.02	0.096	.
Temperature (°C)	0.10	0.12	0.392	
Road Status (Closed)	-0.03	0.05	0.549	.
Season (Calving and Summer)	-3.08	1.68	0.072	
Season (Fall Migration)	0.83	4.59	0.857	
Side of Road (West)	-1.10	3.93	0.780	
Interaction (Calving and Summer * West)	1.46	1.81	0.425	
Interaction (Fall Migration * West)	-0.93	5.07	0.855	

Note: Statistically significant p-values <0.05 are indicated with a single asterisk. Highly significant values ($p < 0.001$) are indicated with three asterisks. Near significant values ($0.09 > p > 0.05$) are indicated with a dot.

The statistics presented include the variable estimate, which can be interpreted as the expected effect on the dependent variable as the independent variable increases. For example, in Table 6.4-1 the positive estimate for temperature suggests that as the temperature increases, the proportion of caribou with response behaviours also increases. However, estimates should always be considered in tandem with the standard error; if the standard error is larger than the estimate, the estimate is meaningless.

The p-value statistic indicates whether the model is a “statistically significant” predictor of the dependent variable, regardless of how large the estimate is. A p-value of less than 0.05 suggests that the variable is an important determinant of the response, as it indicates there was less than 5% probability that the results occurred by chance. A statistically significant result provides support for an underlying effect, but should never be taken without a grain of salt, as some effects can obscure others. To minimize the risk, variables are tested for correlation, but there are always limits when a system is complex. For example, warmer temperatures are observed at the end of spring migration, which is also when convoys are occurring, which may explain the higher proportion of response behaviours in warmer temperatures.

6.4.2 Effect of Distance to Infrastructure

The results suggest that there is a differential effect of distance to the road on response behaviour, as caribou were less likely to be exhibiting response behaviours further from the road (Table 6.4-1). The effect was only significant for caribou within 50-100 m (estimate: 2.85 ± 1.18 , p-value = 0.016), meaning caribou within 100 m of the road are significantly more likely to exhibit response behaviours than caribou more than 1,000 m away. In the response model, no other distance categories were significantly different from the base category of >1,000 m from the road. The effect of distance was not significant for any distance category in the walking model or duration of response model (Tables 6.4-2 and 6.4-3), which suggests that a link between distance to road and response could not be detected in these models. For the duration of response model this may be explained by the smaller sample size.

6.4.3 Effect of Disturbances

The occurrence of disturbances resulted in a statistically significant increase in the proportion of response behaviour (Table 6.4-1; estimate: 1.83 ± 0.53 , p-value = 0.001), but was not important for the proportion of walking behaviour (Table 6.4-2). This may be because the amount of variability in caribou walking is much higher than caribou alert or running. Caribou are more likely to be walking as both a baseline behaviour and a response behaviour, and therefore the effect of disturbances is more difficult to detect in the modelling process. Of note is that the occurrence of disturbances in the interval before and two intervals before was never a significant predictor of behaviour, regardless of model set and how models were parameterized. This may indicate that disturbances tend to only affect behaviour in the 3-minute interval during which they occurred.

6.4.4 Effect of Road Closure Status

Interestingly, road closure status was not a significantly important predictor of behaviour (Tables 6.4-1 to 6.4-3). The models suggest that caribou respond similarly to disturbances regardless of whether the road is open or closed (See Figure 4.3-4). The average proportion of response behaviours was 5% when the road was open and 6% when the road was closed. This may be because the analysis included convoy surveys, which occurred during road closures and had the potential to bias the results. There are typically fewer disturbances during road closures. It may also be simply because the other variables in the model are better at explaining the variation observed in the data.

6.4.5 Effect of Season and Side of the Road (Upstream/Downstream)

Season and side of the road were not significant in the response behaviour model or the duration of response models, but they were important predictors of walking behaviour (Table 6.4-2). Model results indicate that caribou are walking less on the west side of the road in fall migration than in spring migration (estimate: -4.86 ± 2.24 , p-value = 0.03). Since west is upstream of the typical direction of movement in spring, and downstream in fall, another way to interpret this result is that caribou tend to be walking more on the upstream side of the road. In this study, similar numbers of surveys were conducted on the upstream and downstream sides of the road (See Table 6.2-2).

However, an analysis conducted by the GN on the 2019 road survey data from AEM found that most observations of caribou groups were made on the upstream side of the road (GN, Feb 2021 presentation to the TAG). In that presentation, the GN hypothesized that caribou are walking alongside and parallel to the road on the upstream side before crossing, which would be consistent with caribou hesitating to cross the road. More surveys in fall would allow for greater confidence in these results.

6.4.6 Statistical Analysis Summary

The results of the statistical analysis provided support for the key hypothesis that caribou tend to respond to disturbances, particularly when they are close to the road. However, the analysis also found that disturbances did not have a detectable effect on caribou behaviour after three to six minutes. An interesting finding from this analysis included that behaviour was not significantly different when the road was open vs. when it was closed.

The proportion of caribou walking was not linked to disturbances, which suggests that walking is not a consistent response behaviour. However, caribou were significantly more likely to be walking on the upstream side of the road. The results suggest that walking behaviour should not be excluded from analyses. The inclusion of a separate model set for walking behaviour allows for the detection of trends that are not apparent with the alert/running behaviour models.

These results should be treated with caution due to the high number of variables and the variability in the behaviours observed. Nevertheless, these results are consistent with other surveys recorded on barren-ground caribou during the post-calving and early summer periods, which suggest that caribou behavioural responses to all-season haul roads tend to taper off beyond approximately 500 m (Curatolo et al. 1987; Johnson and Lawhead 1989; Dyer et al. 2001). However, zone of influence estimates are highly variable in the literature and this method of data collection is not designed to estimate it, particularly given the observability bias noted in Section 6.3-1. In addition, responses to roads and infrastructure have previously been linked to increased harvest from roadways (Plante et al. 2018; Russell and Gunn 2019), a factor which was not included in this analysis.

7. SUMMARY

The behaviour monitoring data from 2021 were combined with data from 2020, and all results outlined in this report use both years, unless otherwise stated. The program and combined data resulted in several key findings:

- The standard monitoring protocols adapted from the GNWT ENR worked well at the Project site.
- 134 surveys were conducted, compared to 116 in 2020. 114 surveys occurred during spring migration from March to May, 15 occurred during calving and summer from June to August, and five occurred during fall migration from September to December.
- Caribou mostly exhibited the non-response behaviours of standing, laying, feeding, and walking.
- Observations were well distributed across a range of caribou group sizes from one to two individuals to >1,000.
- Larger groups of caribou tended to be recorded further from the road. Only two groups larger than 100 individuals were recorded within 100 m of the road at the start of the survey, both in 2021.
- Caribou group size was not statistically related to response or walking behaviour.
- Statistical analysis indicated that there is a trend for caribou at greater distance from the road (>1,000 m) to have a lower proportion of response behaviours (alert and running) than caribou within 100 m of the road.
- Approximately 70% of the surveys included a disturbance event; typically, haul traffic and light trucks from the mine, and occasionally all-terrain vehicles (ATVs) on the AWAR for travel and harvesting.
- Following a disturbance event, the proportion of response behaviours in a group of caribou was significantly higher, but generally returned to baseline behaviours within one or two sampling intervals (i.e., three or six minutes). Disturbances did not statistically affect the proportion of caribou walking.
- Surveyors conducted special 90-minute surveys during convoys to assess whether the response to convoys was similar to that of other vehicles. Caribou responded similarly to convoys but possibly for longer than for other vehicles. More convoy surveys are needed to analyse the data statistically.
- During periods when large groups of caribou are present, the AWAR and Haul Roads are closed following a decision tree in the Meadowbank Mine Terrestrial Ecosystem Management Plan (TEMP), reducing the potential to record interactions between vehicles and caribou. Road closure status did not affect behaviour in the statistical analysis, possibly due to it having less explanatory power than the other variables included.
- Groups of caribou on both the upstream and downstream sides of the road, but were more commonly observed on the upstream side during spring migration. Statistical analysis found that side of road and season did not affect response behaviour (alert/running), but that caribou were significantly more likely to be walking on the upstream side of the road.
- The updates applied to the survey protocol in 2021 followed comments from the TAG on the first year of data, and were helpful in improving the overall quality and accuracy of the data.

In conclusion, even with some changes to the protocol between 2020 and 2021, the trends in the results were highly consistent between the two years of data. This increases the confidence that trends are repeatable year to year. Overall, the results of the statistical analysis provided support for the key hypothesis that caribou tend to respond to disturbances, particularly when they are close to the road. However, the analysis also found that disturbances did not have a detectable effect on caribou behaviour after three to six minutes. Additional data collection in fall and during convoys would bolster the sample size and improve the likelihood of detecting statistically significant effects.

APPENDIX A MEADOWBANK GOLD MINE: CARIBOU BEHAVIOUR MONITORING DATA SHEET

1. INTRODUCTION

Agnico Eagle Mines Ltd. (Agnico Eagle) would like to determine whether caribou behaviour changes in response to mine activities. The purpose of caribou behaviour surveys is to provide information to characterize the effects of the physical road and mine-related activities on caribou behaviour, including the All Weather Access Road (AWAR) and Haul Road.

The planned monitoring program is designed to collect data on caribou behaviour using standardized, scientifically-defensible methods. The data will be used to monitor Project effects.

1.1 Objectives

Following discussions with the Kivalliq Inuit Association and Government of Nunavut during the spring of 2021, the objectives of the behaviour monitoring program for caribou have been updated to the following:

- Evaluate the baseline behaviour of caribou (behaviour in the absence of disturbance);
- Evaluate the response of caribou to disturbances;
- Compare the behaviour of caribou between the following categories, if there is sufficient data:
 - 1) in large vs. small groups,
 - 2) near vs. far from the road,
 - 3) when the road is open vs. closed,
 - 4) east vs. west of the road, (upstream and downstream), and
 - 5) spring migration vs. summer and fall periods.

2. STUDY AREA

The study area for behaviour monitoring is anywhere that caribou may interact with the mine, including the All Weather Access Road (AWAR), the Meadowbank Mine site, Whale Tail site and the Haul Road connecting Meadowbank to Whale Tail.

3. STANDARD OPERATING PROCEDURES

The purpose of caribou behaviour surveys is to provide information to characterize the effects of the physical road and mine-related activities on caribou behaviour, including the All Weather Access Road (AWAR) and Haul Road. The overall method for the surveys is to identify caribou groups visible from the road, to select some groups for observation, and to record the behaviour of individuals in groups of different sizes including their behaviour without any disturbance and responses to both mine-related activities and natural factors.

Notes to guide the work include:

- Systematic surveys will be conducted along all Project roads during spring, summer and fall periods.
- The survey team will consist of a driver/observer and a second observer when available.

Surveys should be performed:

- During spring, summer and fall when caribou may be in the Project area,
- Of caribou at various distances from the road and group sizes, and
- If surveying effects of a convoy, conduct two surveys, one at least an hour before convoy deployment so that a pre-disturbance measurement can be made, and a second survey during the convoy passing by caribou.

3.1 General Field Data

For each survey day, the appropriate general field data will be recorded onto field data sheets supplied in Appendix A and B. A new data sheet will be used for each survey, including additional sheets as necessary to record all observations. General information includes:

- Survey date and start and end times.
- Field personnel (full names on the data sheet header and initials thereafter).
- Weather conditions during and prior to sampling (e.g., snow in the last 24 hours, current wind conditions).
- Site description: provide location and description (GPS coordinates, road name and distance marker).
- Photographs or video (if possible):
 - Take a photo of the caribou every time an observation is recorded so that the observations can be verified by a biologist.
 - For any photographs taken, record the picture IDs in the comments field on the field data sheet.
 - Write descriptions of any photos taken for specific reasons.
- General observations/notes of the environment/sampling procedures.
- Any deviation from the SOPs outlined below.

Note: When in doubt take pictures and make field notes explaining the situation, your response or consequent changes in methods. It is better to have more data/notes than not enough when interpreting the results later on.

3.2 General Equipment List

- A GPS unit with waypoints of road km markings.
- Field data sheets (Appendix A and B), clipboard, pencils, or iPad with data form.
- A timer capable of alarm setting for repeat time intervals (i.e., can be set to go off every three minutes, like a smart phone).
- Binoculars or spotting scope.
- Compass (or use compass function on GPS unit).
- Portable weather station (temperature and wind speed).
- Camera.
- Rangefinder.

3.3 Field Methods

3.3.1 Group Selection

The survey day will begin with a reconnaissance survey to determine how many caribou groups are present near the road, how large they are, and where they are. This will be accomplished by driving from the mine site along the road and noting relevant information about the groups and their sizes along the way (using the standard, tablet-based road survey form). Observers will preferentially choose groups to survey to across group sizes and distances from the road. Ideally, caribou would be sampled in an even distribution across these variables and along the AWAR and Haul Road. However, the nature of caribou and field sampling mean that observers may need to survey what caribou are available, rather than what is “ideal”.

Allow approximately one hour to survey each group. If the length of the survey day permits all groups to be surveyed then they should all be surveyed. If there are more groups to survey than the time in the day, then do the following:

1. Look at how many of each group size (bullet list below) have been surveyed to date. If one of them is under-represented and there is a group of that size on the road, then go survey that group. If there is more than one group of that size, choose it randomly using the procedure in step 4.
 - 1 or 2 caribou
 - 3 to 25 caribou
 - 26 to 50 caribou
 - >50 caribou
2. During 2020, few groups of caribou within 300 m of the road were observed or sampled. Preferentially choose groups of caribou within 300 m of the road, with a soft target of approximately 1/3 of samples in this area.
3. If any Project-tolerant caribou are observed (e.g., caribou observed near the road or mine site for more than 72 hours in summer and 48 hours in other seasons; TEMP 2020), then select these animals for sampling. In Appendix A data sheet, record that the group is Project tolerant in the notes field.
4. If there are multiple groups available, choose groups to fill in an even distribution of group sizes and distances from roads.

Record all caribou groups observed during the reconnaissance survey in the standard, tablet-based survey form and submit that data along with the results of behaviour monitoring.

3.3.2 Selection of an Observation Site

Find a safe parking location and follow site safety protocols. The observation location may be the vehicle itself or a safe location off the road. If observers exit the vehicle, the observation location should be chosen where observer activity is not likely to influence caribou behaviour and where the observer can remain comfortable for a period of approximately 45 minutes without needing to move. Ideally, the vehicle should be stopped a minimum of ~250-300 m from the caribou – adapt this distance as needed. If the animals are staring at the truck or moving away, then the truck is too close.

3.3.3 Data Recording

Allow 15 minutes between arrival and the time at which behavioural observations begin. This is to allow animals to return to behaviour that may have been interrupted by the arrival of observers. In the time before recording behaviour, fill in the top portion of the form with location, weather, and group size information.

After 15 minutes, begin recording data in the form in Appendix A. The start time to record is the time that observations begin.

3.3.3.1 Location

Location: Collect a waypoint of the location from which the observations will be made. Note the waypoint number and the UTM coordinates on the data sheet.

Road Condition: If observing caribou on a road, record whether the AWAR or Haul Road are open or closed.

Distance: Estimate the distance to the group using a laser rangefinder and, using a compass or the GPS unit compass feature, record the bearing (0° to 360°) to the group being observed. If the group of caribou is large and spread over a considerable distance from the road, estimate the distance to nearby caribou and the caribou furthest away that will be sampled. If some caribou in the group are too far away to sample, then do not include them in the distance estimate.

Behaviour: At each time interval during the survey, observers should record the number of individuals in the group exhibiting behaviour in each category. For clarity, observers should record zero values for behaviours not observed.

East vs. West: Note if the group is on the east or west side of the road. At the end of the 30 minute observation period return to the top of the form and record (Y or N) if the group crossed the road during the survey period. If monitoring at the mine site or Whale Tail, leave this section blank.

Sex: Note the sex of the group. This can be difficult in large groups, so record in the following categories: mostly males, mostly females, mostly females with calves, juveniles, or mixed group.

3.3.3.2 Weather Conditions

Use the portable weather station to record:

- Air temperature;
- Wind speed;
- Wind direction;
- Precipitation; and
- Humidity (if the weather station has this function).

3.3.3.3 Road Structure

At the location of the caribou group, record the road characteristics:

- Height of the road above the tundra (m);
- Slope of the road side (with of the slope in m);
- Approximate height of snow bank (m); and
- Any structures, such as bridges, present.

3.3.3.4 Caribou Behaviour

Individuals in the group being observed will be categorized when the survey starts and at three minute intervals. Standardized behaviour categories will be used (Section 3.3.4). The standardization of behaviour is necessary for clarity and data analysis. If the observed behaviour does not fit within any of the categories then observers have the option of noting other behaviour in the comments field. However, this should be used only rarely as most behaviour should fit in the primary categories listed below. If noting a new/different behaviour, please take a photo or video of the caribou.

The data to record at each three-minute interval are the numbers of individuals in the group exhibiting each behaviour at that time. Do not attempt to characterize the behaviour that occurred during the interval. If the group is too large to be counted in each interval, choose an identifiable subset of the group, count the individuals exhibiting each behaviour at each time interval, and add a comment that a subset of the group was sampled.

Indicate the total group size at the top of the data form, not the size of the subset whose behaviour was recorded. Count the number of caribou up to 100 animals, and then record group size in categories above 100; 100-200 animals, etc. (see Appendix A).

Practically, the easiest way to do this is to have the observer scan across the group of caribou from Left to Right, calling out the behaviour of each animal, while the recorder adds tick marks to the data sheet. When complete, count up the tick marks.

3.3.3.5 Disturbance Events

Caribou behaviour is expected to vary in response to some disturbance events. The bottom of the data form should be used to record any potential disturbance events evident to the observer regardless of whether caribou respond to them. The main categories of events are included in the data sheet:

- Light truck;
- Haul truck;
- Road maintenance vehicle (e.g., grader);
- ATV or skidoo;
- Aircraft; and
- Predator (note species).

Record the number and approximate speed of the vehicle (regular driving speed, or moving slowly, ~10 km/h, past caribou).

Record the time of the disturbance event (0:00 to 30:00 of the survey), indicate which type of disturbance was observed in the appropriate column. Record any additional comments and records of photographs taken in the final column.

Record whether the vehicle stopped when approaching caribou or continued to drive slowly. If possible, coordinate with passing vehicles on the road to have some vehicles stop for 10 minutes, and others drive by slowly.

3.3.4 Behaviour Classification

With the exception of Alert behaviour, the primary behaviour categories and their definitions follow classifications from the Government of Northwest Territories (GNWT 2017). The categories appear as columns on the data form, with descriptions on the form. The behaviour categories are:

- **Feeding** – standing or walking posture, with the muzzle touching or nearly touching the ground; can be ingesting food or not; head down or moving from side to side.
- **Lying down** – bedded on the ground, either upright or lying on its side, in a resting or ruminating position.
- **Standing** – stationary in an upright, standing posture with head elevated above the ground, and usually above the knees; if cow is nursing, if possible record the time spend nursing.
- **Alert** – head up scanning horizon or focused on a source of disturbance (e.g., vehicle, predator, human).
- **Walking** – similar to standing posture but moving at a slow gait (<5 km/h).
- **Trotting/running** – similar to standing posture but moving rapidly in symmetrical or asymmetrical gait.

Other behaviours that may be observed (record in comments field on form) are:

- **Nursing** – calf is suckling cow.
- **Sparring** – two males in contact.
- **Insect response behavior** – twitching, stamping, tossing head.

In the comments, record if any animals are moving towards the road, parallel or away from the road.

4. DATA MANAGEMENT

Please scan all data sheets at the end of the day. Data from behaviour surveys should be entered into Excel. Data from group selection surveys (standard tablet data form) and behaviour surveys should be delivered at the end of each month to ERM for QA/QC.

5. CLOSURE

This SOP has been produced for Agnico Eagle Meadowbank Division by ERM Canada. Please contact the authors with any questions.

Re: Exemption Permit to remove/destroy a raven nest from fuel tank in at mine site near Baker Lake

As per the notification from the Agnico Eagle Mines Limited, it is being requested for permission to remove/destroy a raven's nest on a fuel tank at the site near Baker Lake. The reason for this request is that nest poses a risk to the proper maintenance of the fuel tank and could possibly be a fire hazard.

Ravens and their nests are by law protected. Specifically, by section 72 of the *Wildlife Act* (Nunavut) which states:

72.(1) *Unless lawfully harvesting eggs, no person shall injure, molest or destroy an egg of a bird.*

72.(2) Unless lawfully harvesting down, no person shall injure, molest or destroy

(a) the nest of a bird when the nest is occupied by a bird or its eggs; or

(b) the nest of a bird of prey or prescribed bird.

Also, pursuant to the prescribed matter regulations, ravens are a prescribed bird for the purposes of Section 72(2)(b) of the *Wildlife Act*.

Therefore:

- pursuant to section 72(1) of the *Wildlife Act* it is an offence to injure, molest or destroy a raven egg; and
- pursuant to section 72(2)(a) of the *Wildlife Act* it is an offence to injure, molest or destroy an occupied raven nest; and
- pursuant to Section 72(2)(b) of the *Wildlife Act* it is an offence to injure, molest or destroy an occupied raven nest.
